Summary. Skeletonizing an image is representing a shape with a small amount of information by converting the initial image into a more compact representation and keeping the meaning features. In this paper we use spiking neural P systems to solve this problem. Based on such devices, a parallel software has been implemented on the GPU architecture. Some real-world applications and open lines for future research are also presented.

1 Introduction

Computer vision [32] is probably one of the challenges for computer scientists in the next years. This flourishing research area needs contributions from many other scientific areas as artificial intelligence, pattern recognition, signal processing, neurobiology, psychology or image processing among others. It concerns with the automated processing of images from the real world to extract and interpret information on a real time basis. From a computational point of view, a digital image is a function from a two dimensional surface which maps each point in the surface to a set of features as bright or color. The different treatments of such mappings (digital images) provide a big amount of current applications in computer vision as optical character recognition (OCR), biometrics, automotive safety, surveillance or medical imaging.

In this paper we focus on the problem of skeletonizing an image. Skeletonization is one of the approaches for representing a shape with a small amount of information by converting the initial image into a more compact representation and keeping the meaning features. The conversion should remove redundant information, but it should also keep the basic structure. Skeletonization is usually
considered as a pre-process in pattern recognition algorithms, but its study is also interesting by itself for the analysis of line-based images as texts, line drawings, human fingerprints or cartography.

Many problems in the processing of digital images have features which make it suitable for techniques inspired by nature. One of them is that the treatment of the image can be parallelized and locally solved. Regardless how large is the picture, the process can be performed in parallel in different local areas of it. Another interesting feature is that the local information needed for a pixel transformation can also be easily encoded in the data structures used in Natural Computing. In the literature, we can find many examples of the use of Natural Computing techniques for dealing with problems associated to the treatment of digital images. One of the classic examples is the use of cellular automata [28, 31]. Other efforts are related to artificial neural networks as in [9, 35]. In this paper, we use spiking neural P systems.

Spiking neural P systems (SN P systems, for short) were introduced in [16] as a new class of distributed and parallel computing devices, inspired by the neurophysiological behavior of neurons sending electrical impulses (spikes) along axons to other neurons. SN P systems are the third model of computation in the framework of Membrane Computing\(^1\), together with the cell-like model [25] inspired by the compartmental structure and functioning of a living cell and the tissue-like model [17], based on intercellular communication and cooperation between cells in a tissue.

Recently, Membrane Computing techniques have been used for solving problems from Digital Image. Different P systems models have been used for dealing with images, as in [3] where cell-like P systems are used for computing the thresholding of 2D images; [4, 5, 23, 24] where tissue-like P systems are used, or even [10], where the symmetric dynamic programming stereo (SDPS) algorithm [11] for stereo matching was implemented by using simple P modules with duplex channels. To the best of our knowledge, this is the first time in which SN P systems are used for dealing with images.

In a similar way that other applications of P systems, the theoretical advantages of the Membrane Computing techniques for computer vision need a powerful software and hardware for an effective implementation. In this paper, we also present a parallel software developed by using a device architecture called CUDA\(^{\text{TM}}\), (Compute Unified Device Architecture). CUDA\(^{\text{TM}}\) is a general purpose parallel computing architecture that allows the parallel NVIDIA\(^2\) Graphics Processors Units (GPUs) to solve many complex computational problems in a more efficient way than on a CPU. GPUs constitute nowadays a solid alternative for high performance computing, and the advent of CUDA allows programmers a friendly model to accelerate a broad range of applications. The way GPUs ex-

\(^1\) We refer to [26] for basic information in this area, to [27] for a comprehensive presentation and the P system web page http://ppage.psystems.eu, for the up-to-date information.

exploit parallelism differs from multi-core CPUs, which raises new challenges to take advantage of its tremendous computing power. GPU is especially well-suited to address problems that can be expressed as data-parallel computations.

The paper is organized as follows: Firstly, we present the restricted model of SN P systems used in the paper and recall the Guo & Hall algorithm for skeletonizing images. In Section 4, the design of the SN P system for skeletonizing images is presented. Next, we show illustrative examples of the use of our implementation. Finally, Section 6 is dedicated to conclusions and future work.

2 Spiking Neural P Systems

SN P systems can be viewed as an evolution in Membrane Computing corresponding to a shift from cell-like to neural-like architectures. In SN P systems the processing elements are called neurons and are placed in the nodes of a directed graph, called the synapse graph. The computation is performed by sending electrical impulses among the neurons through the synapses. Such electrical impulses are encoded via a single object type, namely the spike, which is placed in the neurons. The number of copies of such object determines the electrical charge of the neuron. Each neuron may also contain rules which allow to send spikes (possibly with a delay) to other neurons, or to remove a given number of spikes from it (firing and forgetting rules).

Firing rules allow a neuron to send information to other neurons in the form of electrical impulses which are accumulated at the target cell. Forgetting rules remove from the neuron a predefined number of spikes. The application of every rule is determined by checking the contents of the neuron against a regular set associated with the rule. In each time unit, if a neuron can use one of its rules, then one of such rules must be used. If two or more rules could be applied, then only one of them is nondeterministically chosen. Thus, the rules are used in the sequential manner in each neuron, but neurons work in parallel with each other. A global clock is assumed, marking the time for the whole system, and hence the functioning of the system is synchronized.

From the seminal paper [16], other biological features have been explored in the framework of SN P systems. One of such extensions (with mathematical motivation) was introduced in [2], where a neuron can emit more than one spike, if the number of emitted ones is not greater than the consumed ones. Other variants including astrocytes [20], weights, which modify the number of spikes that arrives to a neuron according to the quality of the link between neurons [14, 21, 34], antispikes [22], or neuron division [33] have also been considered. In this paper, we will consider SN P systems with weights in the synapses and rules without delay$^3$.

In this way, the restricted model of SN P systems used in this paper can be formally described as follows. A spiking neural P system of degree $m \geq 1$ is a construct of the form

$^3$ For a more general description, see [16].
where:

1. $O = \{a\}$ is the singleton alphabet (a is called spike);
2. $\sigma_1, \sigma_2, \ldots, \sigma_m$ are neurons, of the form $\sigma_i = (n_i, R_i)$, $1 \leq i \leq m$, where:
   a) $n_i \geq 0$ is the initial number of spikes contained in $\sigma_i$;
   b) $R_i$ is a finite set of rules of the following two forms:
      1) Firing rules $E/a^c \rightarrow a^d$, where $E$ is a regular expression over $a$, and $c \geq d \geq 1$ are integer numbers; if $E = a^b$ (with $b$ an integer number, $b \geq c$), then the rule is usually written in the following simplified form:
         $a^b/a^c \rightarrow a^d$;
      2) Forgetting rules $a^b/a^c \rightarrow \lambda$, for $b$ and $c$ integer numbers with $b \geq c \geq 1$.
3. $syn \subseteq \{1, 2, \ldots, m\} \times \{1, 2, \ldots, m\} \times W$ is the set of synapses between neurons, where the set of weights is $W = \mathbb{Q} \cap [0, 1]$, i.e., the set of rational numbers between 0 and 1. The synapses also verifies that $(i, i, k) \notin syn$ for $1 \leq i \leq m$, $k \in W$.
4. $in$ is the label of the input neuron of $\Pi$.

A firing rule $E/a^c \rightarrow a^d \in R_i$ can be applied in neuron $\sigma_i$ if it contains $b$ spikes, $b \geq c$, and $a^b$ belongs to the language associated to $E$. For applying rules of type $a^b/a^c \rightarrow a^d$, the neuron must contain exactly $b$ spikes. The execution of these rules removes $c$ spikes from $\sigma_i$ (thus leaving the remaining spikes in $\sigma_i$), and sends $d$ spikes to all the neurons $\sigma_j$ such that $(i, j, k) \in syn$. The number of spikes that arrives to the neuron $j$ through the synapse $(i, j, k)$ depends on the number $d$ of emitted spikes and the quality of the synapse, encoded by the weight $k$. In each neuron, the number of spikes after a computation step is the number of non consumed spikes plus the contribution of other neurons via the corresponding synapses. Let us consider that $d$ spikes are emitted through a synapse $(i, j, k)$. The contribution of $\sigma_i$ to $\sigma_j$ is an increase of $[d \times k]$ spikes, where $[v]$ denotes the largest integer not greater than $v$. A forgetting rule $a^b/a^c \rightarrow \lambda$ can be applied in neuron $\sigma_i$ if it contains exactly $b$ spikes. The execution of this rule simply removes all the $c$ spikes from $\sigma_i$ (thus leaving $b - c$ spikes).

A configuration of the system is described by the numbers $(n_1, n_2, \ldots, n_m)$ of spikes present in each neuron. At the beginning of the computation, the number of spikes in each neuron $\sigma_i$ is $n_i$, but in the input neuron (with label $in$): If the input of the computation is $N$, then, in the initial configuration, the number of spikes in the input neuron is $n_{in} + N$.

Example 1. Let us consider the SN P system $\Pi = (\{a\}, \sigma_1, \sigma_2, \sigma_3, syn, 1)$ (see Fig. 1) with $\sigma_1 = (7, R_1)$, $\sigma_2 = (3, R_2)$, $\sigma_3 = (8, R_3)$ and the set of rules and synapses

\footnote{Along this paper, we use regular expressions of type $a^n a^*$, with $n \in \mathbb{N}$. In this case, the language associated to $a^n a^*$ is the set $\{a^{n+k} | k \in \mathbb{N}\}$. For more details about regular expressions, see, for example [29].}
Fig. 1. Example. The input neuron 1 has $9 = 7 + 2$ spikes at the starting configuration.

$$ R_1 = \{ R_{11} \equiv a^5a^*/a^5 \rightarrow a^3 \} $$
$$ R_2 = \{ R_{21} \equiv a^5/a^3 \rightarrow a^2 \} $$
$$ R_3 = \{ R_{31} \equiv a^8/a^3 \rightarrow \lambda , \ R_{32} \equiv a^7/a^2 \rightarrow a^1 \} $$

$$ \text{syn} = \{(1,2,0.7), (2,1,1), (2,3,0.8), (3,2,0.5), (1,3,0.4)\} $$

We will consider the input $N = 2$, so, in order to start the computation, 9 spikes ($7 + 2$) are placed in the neuron 1. Notice that $R_{11}$ will be applied if the neuron 1 contains at least 5 spikes. $R_{31}$ is the unique forgetting rule in the SN P system.

Since the input is $N = 2$, the initial configuration is $C_0 = \langle 9,3,8 \rangle$. From this initial configuration, rules $R_{11}$ and $R_{31}$ can be applied. The rule $R_{11}$ consumes 5 spikes from the neuron 1 and sends 3 spikes to the neurons 2 and 3. These 3 sent spikes are multiplied by the corresponding weights before arriving to the target neurons. The weight of the synapses between the neurons 1 and 2 is $w_{12} = 0.7$, so the application of the rule $R_{11}$ produces an increase of $\lceil 3 \times 0.7 \rceil = 2$ spikes in the neuron 2. Bearing in mind that $w_{13} = 0.4$, the application of the rule $R_{11}$ increases in $\lceil 3 \times 0.4 \rceil = 1$ the number of spikes in the neuron 3. The forgetting rule $R_{31}$ deletes 3 spikes from neuron 3 and hence, the new obtained configuration is $C_1 = \langle 4, 5, 6 \rangle$.

Now, the unique applicable rule is $R_{32}$. This rule consumes 3 spikes from neuron 2 and sends 2 spikes to the neurons 1 and 3. According with the corresponding weights, the number of the spikes in the neuron 1 is increased in $\lceil 2 \times 1 \rceil = 2$ and the number of the spikes in the neuron 3 is increased in $\lceil 2 \times 0.8 \rceil = 1$. By applying these modifications, the obtained configuration is $C_2 = \langle 6, 2, 7 \rangle$. 
From this configuration, rules $R_{11}$ and $R_{32}$ are applicable. The effects of $R_{11}$ have been described above. The rule $R_{32}$ removes 2 spikes from the neuron 3 and sends 1 spike to neuron 2. This spike is multiplied by the corresponding weight, $w_{32} = 0.5$, so it does not produce any increase in the number of spikes in neuron 3, since $\lfloor 0.5 \times 1 \rfloor = 0$. With these changes, the obtained configuration is $C_3 = (1, 4, 4)$. No more rules can be applied and $C_3$ is the halting configuration.

3 Guo & Hall Algorithm

Skeletonization is a common transformation in Image Analysis. The concept of skeleton was introduced by Blum in [1], under the name of medial axis transform. There are many different definitions of the skeleton of a black and white image and many skeletonizing algorithms, but in general, the image $B$ is a skeleton of the image $A$, if it has fewer black pixels than $A$, preserves its topological properties and, in some sense, keeps its meaning. In this paper, we focus on an iterative procedure of thinning: roughly speaking, the border black pixels are removed as long as they are not considered significant. The remaining set of black pixels is called the skeleton (See Fig. 2).

Among the parallel algorithms, special attention deserves the so-called 1-subcycle parallel algorithms or fully parallel algorithms [12]. Our bio-inspired design is based on a classical skeletonizing algorithm, the Guo & Hall algorithm [12, 13]. In this algorithm, the pixels are examined for deletion in an iterative process.

---

5 A detailed description is out of the scope of this paper. For a survey in this topic, see e.g., [30].
First of all, given an $n \times m$ image, it is divided into two sub-sections. One of the sections is composed by the pixels $a_{ij}$ such that $i + j$ is even. Alternatively, the second sub-section corresponds to the pixels $a_{ij}$ such that $i + j$ is odd. The algorithm consists on two sub-iterations where the removal of redundant pixels from both sub-sections are alternated, i.e., in each step only the pixels of one of the subsections are evaluated for its deletion.

The decision is based on a $3 \times 3$ neighborhood. Given a pixel $P_0$, a clockwise enumeration $P_1, \ldots, P_8$ of its eight neighbor pixels is considered, (Figure 3 (Left)). As usual, for each $i \in \{1, \ldots, 8\}$, $P_i$ is considered as a Boolean variable, with the truth value 1 if $P_i$ is black and 0 if $P_i$ is white.

In order to decide if a pixel $P_0$ is deleted in the corresponding iteration sub-cycle, two parameters are evaluated:

\[
B(P_0) = \sum_{i=1}^{8} P_i \\
C(P_0) = (\neg P_2 \land (P_3 \lor P_4)) + (\neg P_4 \land (P_5 \lor P_6)) + (\neg P_6 \land (P_7 \lor P_8)) + (\neg P_8 \land (P_1 \lor P_2))
\]

$B(P_0)$ counts how many pixels in the neighborhood of $P_0$ are black. $C(P_0)$ evaluates the connectivity of the pixel $P_0$. Notice that for isolated black pixels, the connectivity is 0, and for pixels surrounded by eight black pixels, the connectivity is 4.

According to the Guo & Hall algorithm, in each iteration, an evaluated black pixel $P_0$ is deleted (changed to white) if and only if all of the following conditions are satisfied.

**Guo & Hall conditions:**

1. $B(P_0) > 1$;
2. $C(P_0) = 1$; This condition is necessary for preserving local connectivity when $P$ is deleted.
3. $(P_1 \land P_3 \land P_5 \land P_7) \lor (P_2 \land P_4 \land P_6 \land P_8) = \text{FALSE}$; Intuitively, this condition is satisfied if $P_0$ is not the central pixel of a cross.
For example, let us consider as \( P_0 \) the central pixel in the image of Fig. 3 (Center). In this case, \( B(P_0) = 3 > 1 \), \( C(P_0) = 1 \), and the third condition is also satisfied. Hence, \( P_0 \) will be deleted in the corresponding sub-cycle iteration.

4 SN P Systems for Skeletonizing

In this paper we will show how to use SN P systems for skeletonizing images. In particular, we use SN P systems for implementing the Guo & Hall algorithm. Without losing generality, we will consider each image as a mapping \( I : \{ 1, \ldots, p \} \times \{ 1, \ldots, q \} \rightarrow \{ \text{black}, \text{white} \} \), with \( I(1,k) = I(p,k) = I(j,1) = I(j,q) = \text{white} \) for all \( k \in \{ 1, \ldots, q \} \) and \( j \in \{ 1, \ldots, p \} \), i.e., the image has \( n \times m \) pixels and all the pixels on the border are white.

Given a pixel \((i,j)\), we can use the enumeration of the pixels used in the previous section to represent the neighborhood of the pixel \( P_0 \) in \((i,j)\). Such a neighborhood will be represented as a list \([H_0, \ldots, H_8]\), where, for \( r \in \{ 0, \ldots, 8 \} \), \( H_r = 1 \) if \( P_r \) is a white pixel and \( H_r = 0 \) if \( P_r \) is a black one\(^6\). This representation of the neighborhood can be done in a more compact way, by encoding the neighborhood as a number\(^7\) in \( \{ 0, \ldots, 511 \} \).

\[
\text{cod}(i,j) = \sum_{r=0}^{8} H_r \times 2^r
\]

For example, in Fig. 3 (Center), the \( 3 \times 3 \) neighborhood can be encoded as \([0, 0, 0, 0, 0, 0, 1, 1, 1]\), or, shortly, \( 2^4 + 2^5 + 2^6 + 2^7 + 2^8 = 496 \).

Since the decision of removing a black pixel (changing to white) depends on its \( 3 \times 3 \) neighborhood and there is a bijective correspondence among the sets of all the possible neighborhoods and the possible encodings \( \{ 0, \ldots, 511 \} \), it is easy to check that the pixel in \((i,j)\) must be removed if it belongs to the set

\[
DEL = \{ 6 \ 12 \ 14 \ 18 \ 24 \ 26 \ 28 \ 30 \ 36 \ 38 \ 44 \ 46 \\
48 \ 50 \ 56 \ 58 \ 60 \ 62 \ 66 \ 72 \ 74 \ 96 \ 98 \ 104 \\
106 \ 112 \ 114 \ 120 \ 122 \ 124 \ 126 \ 132 \ 134 \ 140 \ 142 \ 144 \\
146 \ 152 \ 154 \ 156 \ 158 \ 164 \ 166 \ 172 \ 174 \ 176 \ 178 \ 184 \\
186 \ 188 \ 190 \ 192 \ 194 \ 200 \ 202 \ 222 \ 224 \ 226 \ 232 \ 234 \ 240 \\
242 \ 248 \ 250 \ 252 \ 258 \ 262 \ 264 \ 266 \ 270 \ 286 \ 288 \ 290 \\
294 \ 296 \ 298 \ 302 \ 318 \ 384 \ 390 \ 392 \ 394 \ 398 \ 414 \\
416 \ 418 \ 422 \ 424 \ 426 \ 430 \ 448 \ 450 \ 454 \ 456 \ 458 \ 462 \\
480 \ 482 \ 486 \ 488 \ 490 \ 496 \ 498 \ 504 \}
\]

The complementary set of encodings will be denoted by \( \overline{DEL} \), in other words,

\(^6\) Notice that we encode black pixels as 0 and white pixels as 1 for an easier implementation with SN P systems. In the previous section, we keep the opposite encoding in order to keep continuity with the literature.

\(^7\) Similar ideas are also used in [30].
\[ \mathcal{DEL} = \{ s \in \{0, \ldots, 511\} \mid s \not\in \mathcal{DEL} \} \]

For each image of size \( p \times q \), a SN P system will be provided. The input of the SN P system is a non negative integer which represents the number of iterations in the skeletonizing process. Formally, given an \( p \times q \) image, we associate to it the following SN P system is degree \((p \times q) + 2\):

\[ II = (O, \sigma_{11}, \sigma_{12}, \ldots, \sigma_{pq}, \sigma_{\text{odd}}, \sigma_{\text{even}}, \text{syn}, \text{odd}) \]

i.e., a SN P system with a neuron for each pixel in the image plus two extra neurons, \( \sigma_{\text{odd}} \) and \( \sigma_{\text{even}} \). The input neuron is \( \sigma_{\text{odd}} \).

- \( O = \{a\} \) is the singleton alphabet;
- \( \sigma_{\text{odd}} = (512, a^{513} a^* / a^{513} \rightarrow a^{512}) \) and \( \sigma_{\text{even}} = (0, a^{512} / a^{512} \rightarrow a^{512}) \);
- \( \sigma_{ij} = (n_{ij}, R_{ij}), \, i \in \{1, \ldots, p\}, \, j \in \{1, \ldots, q\} \), where
  \[ n_{i,j} = \begin{cases} 0 & \text{if } i = 1 \vee i = p \vee j = 1 \vee j = q \\ \text{cod}(i,j) & \text{otherwise} \end{cases} \]

\[ R_{1k} = R_{ph} = R_{j1} = R_{jq} = \emptyset \text{ for all } k \in \{1, \ldots, q\} \text{ and } j \in \{1, \ldots, p\}. \]

- For the remaining \((i,j)\),
  \[ R_{ij} = \{a^b / a^{511} \rightarrow a^{256} \mid b = r + 512 \land r \in \mathcal{DEL}\} \cup \{a^b / a^{512} \rightarrow \lambda \mid b = r + 512 \land r \in \mathcal{DEL}^c\} \]

- \( \text{syn} = \bigcup_{i=2}^{p-1} \bigcup_{j=2}^{q-1} \text{syn}_{ij} \)
  \[ \cup \text{syn}_{\text{odd}} \cup \text{syn}_{\text{even}} \cup \{\{\text{odd}, \text{even}, 1\}, \{\text{even}, \text{odd}, 1\}\}, \]

where

\[ \text{syn}_{\text{odd}} = \{\{(i,j), 1\} \mid i \in \{2, \ldots, p-1\}, j \in \{2, \ldots, q-1\}, \, i + j \text{ odd}\} \]

\[ \text{syn}_{\text{even}} = \{\{(i,j), 1\} \mid i \in \{2, \ldots, p-1\}, j \in \{2, \ldots, q-1\}, \, i + j \text{ even}\} \]

and for all \( i \in \{2, \ldots, q-1\}, j \in \{2, \ldots, q-1\}, \)

\[ \text{syn}_{ij} = \{((i,j), (i+1,j), 1/2^6), ((i,j), (i-1,j), 1/2^4), \}
\[ ((i,j), (i+1,j+1), 1/2^4), ((i,j), (i-1,j-1), 1/2^5), \}
\[ ((i,j), (i,j+1), 1/2^2), ((i,j), (i,j-1), 1/2^6), \}
\[ ((i,j), (i-1,j+1), 1/2^3), ((i,j), (i+1,j-1), 1/2^7)\} \]

The SN P system has one neuron \( \sigma_{ij} \) for each pixel of the image plus two extra neurons \( \sigma_{\text{odd}} \) and \( \sigma_{\text{even}} \). The neurons corresponding to the border of the image has zero spikes in the initial configuration, the remaining neurons \( \sigma_{ij} \) corresponding to the pixels of the image (called hereafter, the regular neurons) have \( \text{cod}(i,j) \) spikes in the initial configuration. The neurons \( \sigma_{\text{odd}} \) and \( \sigma_{\text{even}} \) have 512 and 0 spikes.
respectively. We will add to the 512 spikes in $\sigma_{\text{odd}}$ as many spikes as indicated as input for starting the computation.

The neuron $\sigma_{\text{odd}}$ has only one rule $a_{513}^1 a^* / a_{513} \rightarrow a_{512}^1$ which is applied if the neuron has at least 513 spikes. The neuron $\sigma_{\text{even}}$ has also one rule $a_{512}^1 / a_{512} \rightarrow a_{512}^1$.

The regular neurons have two types of rules: Firing and forgetting ones, which will be applied if the number of spikes is exactly $b = r + 512$ with $r \in \text{DEL}$ or $r \in \text{DEL}$, respectively.

With respect to the synapses, a regular neuron corresponding to a pixel $P$ is linked to the eight neurons corresponding to the eight neighbor pixels of $P$, with the weights $1 / 2^i$ where $i \in \{0, \ldots, 7\}$ follows an anti-clockwise enumeration of the pixels starting in the east pixel (see Fig. 3 (Right)). The neurons $\sigma_{\text{odd}}$ and $\sigma_{\text{even}}$ are linked each other. The neuron $\sigma_{\text{odd}}$ is also linked to all the regular neurons $\sigma_{ij}$ with $i + j$ odd and, analogously, $\sigma_{\text{even}}$ is linked to all the regular neurons $\sigma_{ij}$ with $i + j$ even.

### 4.1 How it works

In order to understand how the SN P system works, firstly we observe that at the initial configuration, the set of regular neurons $\sigma_{ij}$ encodes the image which will be skeletonized. We will show that, at any time, these neurons encode the successive images obtained in the iterative process of deleting black pixels according to the Guo & Hall algorithm. Let us remark that if the number of spikes in $\sigma_{ij}$ is even, then the corresponding pixel is black; otherwise, if the number of spikes is odd, then the corresponding pixel is white. This is easily derived from the definition of $\text{cod}(i, j)$.

Another observation to be considered is that the parity of the number of spikes in a neuron never changes, since the number of spikes received or removed is always an even amount, except by the application of the rule $a_{511}^b / a_{511}^b \rightarrow a_{256}^b$. As we will see below, the application of this rule is interpreted as the deletion of the corresponding black pixel in the Guo & Hall algorithm and it is applied once at most in each neuron.

Before explaining the different steps of the process, let us consider a pixel $(i, j)$ in the image and a black pixel adjacent to $(i, j)$. We identify this black pixel to $v \in \{P_1, \ldots, P_8\}$ according to the clockwise enumeration described above. Let us suppose that the black pixel in $v$ belongs to the selected subsection in the current step of the Guo & Hall algorithm and it satisfies the conditions to be deleted.

Let us consider now the neurons $\sigma_{ij}$ and $\sigma_v$ corresponding to the pixels in $(i, j)$ and $v$. As we will show below, the three conditions for $v$ (it is black, it belongs to a selected subsection and it satisfies the Guo & Hall conditions to be deleted) indicates that the number of spikes in $\sigma_v$ is $b = r + 512$ with $r \in \text{DEL}$. In this case the rule $a_{511}^b / a_{511}^b \rightarrow a_{256}^b$ is applied. As pointed out above, the application of this rule changes the parity of the number of spikes $\sigma_v$ (from even, since the pixel is black, to odd) and this change is interpreted as a deletion of the pixel in $v$.

We focus on the influence of the deletion of the black pixel in $v$ (or, equivalently, the application of the rule $a_{511}^b / a_{511}^b \rightarrow a_{256}^b$ in $\sigma_v$) on the neuron $\sigma_{ij}$. Since the
number of spikes in $\sigma_{ij}$ at the initial configuration is $\text{cod}(i, j) = \sum_{i=0}^{8} Hi \times 2^i$ and, in this configuration, the pixel $v$ is black, according to the encoding, this means that $Hv$ is zero, or, in other words, $2^v$ does not appear in the encoding of the environment as an addition of powers of 2.

The deletion of the pixel in $v$ changes the environment of $(i, j)$ and then, since the number of spikes in $\sigma_{ij}$ represents such environment, the number of spikes must change. In particular, the change corresponds to turn $Hv$ to 1, or, in other words, to add $2^v$ to the number of spikes in $\sigma_{ij}$.

In order to check that this happens, it is suffices to seen that the rule $a^8/a^{511} \rightarrow a^{256} = 2^8$ from neuron $\sigma_v$ to $\sigma_{ij}$, but these $2^8$ must be multiplied by the corresponding weight in $\{1/2^0, \ldots, 1/2^7\}$, so only $2, 2^2, 2^3, \ldots, 2^7$ or $2^8$ spikes arrive to $\sigma_{ij}$, depending on the value of $v$. A simple inspection shows that the number of spikes that arrives to $\sigma_{ij}$ is exactly $2^v$ when the black pixel $v$ is deleted.

Bearing in mind these considerations, we show that for an input $N \in \{1, \ldots, 513\}$, the computation steps of the SN P system correspond to the iterative process of the Guo & Hall algorithm where the first selected subsection corresponds to pixels with $i + j$ odd. In such way we will show the following statements:

- **Statement 1:** The set of regular neurons is split into two sub-sections. One of the sections is composed by the neurons $\sigma_{ij}$ such that $i + j$ is even. Alternatively, the second sub-section corresponds to the neurons $\sigma_{ij}$ such that $i + j$ is odd. Both subsections are alternatively selected, starting with the odd subsection.

- **Statement 2:** In each computation step, only neurons corresponding to the selected subsection are evaluated. The evaluation consists on determining if the neighborhood of the pixel associated to the neuron satisfies the conditions of the Guo & Hall algorithm to be deleted.

- **Statement 3:** If an evaluated black pixel satisfies the Guo & Hall conditions to be deleted (see Section 3), then the number of spikes in the corresponding neuron changes from even to odd.

- **Statement 4:** In each configuration, the number of spikes in the regular neurons is the codification of an image, according to the encoding described above.

The first key point of the algorithm is that the image is split into two subsections which will be explored alternatively. One black pixel will be considered for its deletion only if it belongs to the subsection selected in the current step. We consider that a regular neuron $\sigma_{ij}$ is selected at the step $r$ if its number of spikes in the configuration $C_r$ is greater than or equal to 512. Otherwise, if its number of spikes is lower than 512, then the neuron is not selected.

Next we show that the regular neurons with $i + j$ odd and even are alternatively selected. The selection of subsections is performed by the neurons $\sigma_{odd}$ and $\sigma_{even}$ which send, alternatively, 512 spikes to the regular neurons $\sigma_{ij}$ with $i + j$ odd and even, respectively.

**Lemma 1.** Let $\sigma_{ij}$ be a regular neuron and $N \in \{1, \ldots, 513\}$ the input of the SN P system. For $r \in \{0, \ldots, N - 1\}$
If $i + j$ is odd, then the number of spikes in $\sigma_{ij}$ is greater than or equal to 512 in the configuration $C_{2r+1}$ and it is lower than 512 in the configuration $C_{2r}$.

If $i + j$ is even, then the number of spikes in $\sigma_{ij}$ is greater than or equal to belongs to 512 in the configuration $C_{2r+2}$ and it is lower than 511 in the configuration $C_{2r+1}$.

**Proof.** Let us observe that in the initial configuration, the number of spikes in a regular neuron $\sigma_{ij}$ is $\text{cod}(i, j) < 512$; the number of spikes in $\sigma_{odd}$ is $512 + N$ and there is zero spikes in the neuron $\sigma_{even}$. From this initial configuration, the unique applicable rule is $a^{513}a^*/a^{513} \rightarrow a^{512}$ in the neuron $\sigma_{odd}$ (since $N \geq 1$).

After applying this rule, in the configuration $C_1$, the number of spikes in $\sigma_{odd}$ is $N - 1$; the number of spikes in $\sigma_{even}$ is 512; and the number of spikes in $\sigma_{ij}$ is $\text{cod}(i, j) + 512$ if $i + j$ is odd and $\text{cod}(i, j)$ if $i + j$ is even.

Let us focus now on $\sigma_{odd}$ and $\sigma_{even}$. The unique neuron that sends spikes to $\sigma_{odd}$ is $\sigma_{even}$ and, analogously, the unique neuron that sends spikes to $\sigma_{even}$ is $\sigma_{odd}$. In the configuration $C_1$, the spikes in $\sigma_{odd}$ and $\sigma_{even}$ are $N - 1$ and 512, respectively. Since $N \leq 513$, the rule in $\sigma_{odd}$ cannot be applied in this configuration, but the rule in $\sigma_{even}$ can be applied, so the spikes in $\sigma_{odd}$ and $\sigma_{even}$ in the configuration $C_2$ are $512 + N - 1$ and 0, which is similar to the situation in the initial configuration, so we have that for $r \in \{1, \ldots, N\}$, the number of spikes in $\sigma_{odd}$ and $\sigma_{even}$ and in the configuration $C_{2r}$ are $512 + N - r$ and 0.

Notice that at the configuration $C_{2N}$, the number of spikes in $\sigma_{odd}$ and $\sigma_{even}$ are 512 and 0, respectively, and no more rules are applied in these neurons.

According to the number of spikes in $\sigma_{odd}$ and $\sigma_{even}$ in the odd and even configurations, and taken into account their synapses, then we have that, for $r \in \{0, \ldots, N - 1\}$, at the configuration $C_{2r+1}$, the regular neurons with $i + j$ odd has at least 512 spikes; and at $C_{2r+2}$, the regular neurons $\sigma_{ij}$ with $i + j$ even has at least 512 spikes.

In order to complete the proof, it is necessary to prove that for $r \in \{0, \ldots, N - 1\}$, at the configuration $C_{2r+1}$, the regular neurons with $i + j$ odd has at most 511 spikes; and at $C_{2r+2}$, the regular neurons $\sigma_{ij}$ with $i + j$ odd has at most 511 spikes.

Let us start by considering a regular neuron $\sigma_{ij}$ with $i + j$ odd at the configuration $C_1$. As we show above, its number of spikes is $b = 512 + r$ with $r = \text{cod}(i, j) \leq 511$. Depending on $r \in \text{DEL}$ or $r \in \text{DEL}$, one of the rules $a^b/a^{511} \rightarrow a^{506}$ or $a^b/a^{512} \rightarrow \lambda$ is applied.

Let us suppose that $r \in \text{DEL}$. In particular, this means that the corresponding pixel is black and the applied rule is $a^b/a^{511} \rightarrow a^{506}$. The number of spikes in the configuration $C_2$ is equal to the spikes in the configuration $C_1$ (512 + $r$), minus the consumed ones 511 plus the contribution of other neurons. Since $\sigma_{odd}$ does not send any spike in this step, the unique contribution to the number of spikes comes from other regular neurons. Each contribution is the addition of 2 spikes to the spikes in $\sigma_{ij}$, but, bearing in mind that the pixel is black, then 2$^b$ does not appears in the decomposition of $\text{cod}(i, j)$ as sum of powers.
of 2, and it cannot be added as a contribution of other neuron, so \( r \) plus the contribution of other neurons is at most 510 and then, the number of spikes in \( \sigma_{ij} \) in \( C_2 \) is lower than 512.

- If \( r \not\in \text{DEL} \), then the rule \( a^b/a^{512} \rightarrow \lambda \) is applied. Since 512 spikes are consumed and \( r \) plus the contributions of the other regular neurons is at most 511, then the number of spikes in \( \sigma_{ij} \) is lower than 512, also in this case.

This reasoning can be also applied to show that the number of spikes of the neurons \( \sigma_{ij} \) with \( i+j \) even is lower than 512 in the configuration \( C_3 \) and in general we have that for \( r \in \{0, \ldots, N-1\} \), at the configuration \( C_{2r+1} \), the regular neurons with \( i+j \) even has at most 511 spikes; and at \( C_{2r+2} \), the regular neurons \( \sigma_{ij} \) with \( i+j \) odd has at most 511 spikes.

The previous lemma shows that the property to have at least 512 spikes changes alternatively from neurons \( \sigma_{ij} \) with \( i+j \) odd and even. From this result, it is easy to check the second statement, since the rules in the regular neurons can only be applied if the number of spikes is at least 512. That means that only in such cases the neuron is considered for evaluation.

Evaluating a neuron consists on deciding if the rule \( a^b/a^{511} \rightarrow a^{256} \) or \( a^b/a^{512} \rightarrow \lambda \) is applied, but such decision depends on the set \( \text{DEL} \) which are the set of encodings of the neighborhood such that the central pixel must be deleted.

The next key point of the algorithm is the deletion of pixels. By definition of \( \text{cod}(i,j) \), a regular neuron \( \sigma_{ij} \) has an odd number of spikes if and only if it represents a white pixel. Analogously, a regular neuron \( \sigma_{ij} \) has an odd number of spikes if and only if it represents a white pixel. Bearing in mind this coding of black pixels, deleting a black pixel in a computation step consists on removing an odd amount of spikes from a neuron with an even amount of spikes.

**Lemma 2.** Let us consider a black pixel and a step of the Guo & Hall algorithm, such that the pixel belongs to the selected subsection and it satisfies the conditions of the algorithm to be deleted. Then, in the corresponding step of the SN P system computation, the corresponding regular neuron \( \sigma_{ij} \) will pass from an odd amount of spikes to an even amount.

**Proof.** According to the previous construction, a black pixel which belongs to the selected subsection in the Guo & Hall algorithm and verifies the conditions to be deleted has associated a regular neuron with 512 + \( r \) spikes, \( r \in \text{DEL} \). In this case, the rule \( a^b/a^{511} \rightarrow a^{256} \) is applied. Bearing in mind that \( r \) is even, the contributions of other neurons is even and an odd number of spikes is consumed, in the next configuration, the number spikes in the neuron is odd.

Since all the \( r \in \text{DEL} \) are even and the contribution of other neurons is always even, then the rule \( a^b/a^{511} \rightarrow a^{256} \) with \( b = 512 + r \) is applied at most once in each neuron. This means that if a pixel is deleted (changed from black to white), it never becomes black to white, and the iterative process of thinning the image is also carried out in the SN P system.

Finally, to sum up these statements. We claim the following result.
Theorem. The set of regular neurons of the SN P system encodes in each configuration the successive images obtained in the iterative process of thinning of the Guo & Hall algorithm, by taking as black the pixels with an even amount of spikes and white the neurons with an odd amount of spikes.

5 Experimental Simulation

Simulation of different variants of P systems have been widely studied in the last years. Since there do not exist implementations of P systems in vivo nor in vitro, the natural way to explore the behavior of designed P systems is to simulate it in conventional computers. A short description of some of these simulators can be found in [7, 15]. Currently, a big effort is being developed in the P-lingua project [8], by combining an efficient simulation engine with an ad-hoc programming language.

In this paper, a software tools based on the design of the SN P system has been implemented by using CUDA™, (Compute Unified Device Architecture) [18, 19]. CUDA™ is a general purpose parallel computing architecture that allows the parallel NVIDIA Graphics Processors Units (GPUs) to solve many complex computational problems in a more efficient way than on a CPU.

The experiments have been performed on a computer with a CPU AMD Athlon II x4 645, which allows to work with four cores of 64 bits to 3.1 GHz. The computer has four blocks of 512KB of L2 cache memory and 4 GB DDR3 to 1600 MHz of main memory.

The used graphical card (GPU) is an NVIDIA Geforce GT240 composed by 12 Stream Processors with a total of 96 cores to 1340 MHz. It has 1 GB DDR3 main memory in a 128 bits bus to 700 MHz. So, the transfer rate obtained is by 54.4
Fig. 5. Example of image with traffic signals

Gbps. The used Constant Memory is 64 KB and the Shared Memory is 16 KB. Its Compute Capability level is 1.2 (from 1.0 to 2.1). The implementation deals with $N$ blocks of threads for the complete image in our GPU of 96 cores, as we can see in Fig. 4. We need more threads than pixels if the height and width of the image are not multiples of 16; i.e., we can have useless threads (see Figure 4).

5.1 Examples

A first example is shown in Fig 2. Skeletonizing hand-written texts is one of the challenges of skeletonizing, since the skeleton keeps the topological structure and meaning of the original and the text can be easily stored.

Next, we provide several examples of a realistic recognizing problem with applications in the automotive industry. In Fig. 5, we can see a photograph taken in a road. It has been binarized by using a threshold method by using a threshold 100 on a gray scale $0,\ldots,255$. We can see that the skeletonized images keep the information of the traffic signals and they can be used in a further pattern recognition problem (see Fig. 6). In Fig. 7, two more examples of skeletonizing real images are shown.

We finish this section by showing the results of some experiments performed with our implementation. We have taken 36 totally black images of $n \times n$ pixels, from $n = 125$ to $n = 4500$ with a regular increment of 125 pixels of side. Figure 8 (top) shows the time in milliseconds of our software tool inspired in the designed SN P system for implementing the Guo & Hall algorithm for 1, 30, 60 and 90 steps in the skeletonizing process. Figure 8 (bottom) shows the same study for a sequential implementation of the algorithm.

\footnote{Theoretically, this is the worst case, since the time inverted by the algorithm depends on the size of the biggest black connected component of the original image.}

6 Conclusions

The development of new bioinspired parallel techniques provides a chance for revisiting classical sequential algorithms. In this paper, we have consider a classical algorithm for skeletonizing images, but many other algorithms can be considered. In particular, the bio-inspired computing techniques have features as the encapsulation of the information, a simple representation of the knowledge and parallelism, which are appropriate with dealing with digital images.

Nonetheless, the use of new computational paradigms for developing the bio-inspired ideas needs, on the one hand, the contribution of theoretical research that allows us to design new bio-inspired efficient algorithms, and, on the other hand, the use of the most recent parallel computer architectures for a real parallel implementation of the algorithms.

In this paper we provide a new step in both directions, since we study the skeletonization of images by using Spiking Neural P systems and show the results of a new software based on the SN P system by using the GPU architecture. This research line can be followed by considering more classical problems and studying the possible improvements from a bio-inspired perspective, or, by studying the same skeletonization problem in other P system models.
