Summary. A kernel P system (kP system, for short) integrates in a coherent and elegant manner many of the P system features most successfully used for modelling various applications and, consequently, it provides a framework for analyzing these models. In this paper, we illustrate the modeling capabilities of kernel P systems by showing how other classes of P systems can be represented with this formalism and providing a number of kP system models for sorting algorithms. Furthermore, the problem of testing systems modelled as kP systems is also discussed and a test generation method based on automata is proposed. We also demonstrate how formal verification can be used to validate that the given models work as desired.

1 Introduction

Membrane systems were introduced in [27] as a new natural computing paradigm inspired by the structure and distribution of the compartments of living cells, as well as by the main bio-chemical interactions occurring within compartments and at the inter-cellular level. They were later also called P systems. An account of the basic fundamental results can be found in [28] and a comprehensive description of the main research developments in this area is provided in [29]. The key challenges of the membrane systems area and a discussion on some future research directions, are available in a more recent survey paper [20].

In recent years, significant progress has been made in using P systems to model and simulate systems and problems from various areas. However, in order to facilitate the modelling, in many cases various features have been added in an ad-hoc manner to these classes of P systems. This has led to a multitude of P systems variants, without a coherent integrating view. The newly introduced concept of
kernel P systems (kP systems) [16, 17] provides a response to this problem. A kP system integrates in a coherent and elegant manner many of the P system features most successfully used for modelling various applications and, consequently, it provides a framework for analyzing these models. Furthermore, the expressive power of these systems has been illustrated by a number of representative case studies [19, 17]. The kP system model is supported by a modelling language, called kP-Lingua, capable of mapping a kP system specification into a machine readable representation. Furthermore, kP systems are supported by a software framework, kPWorkbench [21], which integrates a set of related simulation and verification tools and techniques.

Another complementary method to simulation and verification is testing, a major activity in the lifecycle of software systems. In practice, software products are almost always validated through testing. Testing has been discussed for cell-like P systems and various strategies, such as rule coverage based and automata based techniques, have been proposed [15, 24]. Until now, however, testing has not been discussed in the context of kP systems.

In this paper we further illustrate the modeling capabilities of kernel P systems by showing that other classes of P systems can be represented with this formalism and by providing a number of kP system models for sorting algorithms. We present in this paper the relationship between kP systems and active membrane systems with electrical charges, whereas in [16, 17, 18] we have also investigated the relationship with neural-like P systems. We also study here the relationship between kP systems and P systems with symport/antiport rules. Furthermore, the problem of testing systems modelled as kP systems is also discussed and a test generation method based on automata is proposed. We also demonstrate how formal verification can be used to validate that the given models work as desired.

2 kP Systems - Main Concepts and Definitions

We consider that standard P system concepts such as strings, multisets, rewriting rules, and computation are well-known and refer to [28] for their formal notations and precise definitions. The kP system concepts and definitions introduced below are from [16, 17]; some are slightly changed and this will be mentioned.

**Definition 1.** $T$ is a set of compartment types, $T = \{t_1, \ldots, t_s\}$, where $t_i = (R_i, \sigma_i)$, $1 \leq i \leq s$, consists of a set of rules, $R_i$, and an execution strategy, $\sigma_i$, defined over $\text{Lab}(R_i)$, the labels of the rules of $R_i$.

**Remark 1.** The compartments that appear in the definition of the kP systems will be instantiated from these compartment types. The types of rules and the execution strategies will be discussed later.

**Definition 2.** A kernel P (kP) system of degree $n$ is a tuple

$$k\Pi = (A, \mu, C_1, \ldots, C_n, i_0),$$
where \( A \) is a finite set of elements called objects; \( \mu \) defines the initial membrane structure, which is a graph, \( (V,E) \), where \( V \) are vertices indicating components, and \( E \) edges; \( C_i = (t_i, w_i), \ 1 \leq i \leq n \), is a compartment of the system consisting of a compartment type from \( T \) and an initial multiset, \( w_i \) over \( A \); \( i_o \) is the output compartment where the result is obtained.

### 2.1 kP System Rules

The discussion below assumes that the rules we refer to belong to the same compartment, \( C_i \).

Each rule \( r \) may have a guard \( g \) which refers to the multiset where the rule is applied to. Its generic form is \( r \{g\} \). The rule \( r \) is applicable to a multiset \( w \) when its left hand side is contained into \( w \) and \( g \) is true for \( w \).

The guards are constructed using multisets over \( A \), as operands, and relational and Boolean operators. Let us first introduce some notations.

For a multiset \( w \) over \( A \) and an element \( a \in A \), we denote by \( |w|_a \) the number of objects \( a \) occurring in \( w \). Let us denote \( Rel = \{<,\leq,=,\neq,\geq,>\} \), the set of relational operators, \( \gamma \in Rel \), a relational operator, \( a^n \) a multiset and \( r \{g\} \) a rule with guard \( g \). We first introduce an abstract relational expression which is evaluated for any multiset where the rule is applied to.

**Definition 3.** If \( g \) is the abstract relational expression \( \gamma a^n \) and \( w \) is the multiset it refers to, then the guard denotes the relational expression \( |w|_a \gamma n \). The guard \( g \) is true for the multiset \( w \) if \( |w|_a \gamma n \) is true.

One can consider the Boolean operators \( \neg \) (negation), \( \wedge \) (conjunction) and \( \vee \) (disjunction), listed with respect to the decreasing precedence order. Abstract Boolean expressions are obtained by connecting abstract relational expressions by Boolean operators.

**Definition 4.** If \( g \) is the abstract Boolean expression and the current multiset is \( w \), then the guard denotes the Boolean expression for \( w \), obtained by replacing abstract relational expressions with relational expressions for \( w \). The guard \( g \) is true for the multiset \( w \) when the Boolean expression for \( w \) is true.

**Definition 5.** A guard is: (i) one of the Boolean constants \( true \) or \( false \); (ii) an abstract relational expression; or (iii) an abstract Boolean expression.

**Example 1.** If \( g \) is the guard \( \geq a^5 \wedge \geq b^3 \vee \neg > c \) and \( w \) a multiset it refers to, then \( g \) is true in \( w \) if it has at least 5 \( a \)’s and 3 \( b \)’s or no more than one \( c \).

**Definition 6.** A rule from a compartment \( C_i = (t_i, w_i) \) can have one of the following types:

- **(a) rewriting and communication rule:** \( x \rightarrow y \{g\} \), where \( x \in A^* \) and \( y \) has the form \( y = (a_1,t_1)\ldots(a_h,t_h) \), \( h \geq 0 \), \( a_j \in A \) and \( t_j \) indicates a compartment type from \( T \) — see Definition 2 — with instance
compartments linked to the current compartment; \(t_j\) might also indicate the type of the current compartment, \(t_{i_j}\). (in this case it is not present on the right hand side of the rule); if a link does not exist (i.e., there is no link between the two compartments in \(E\)) then the rule is not applied; if a target, \(t_j\), refers to a compartment type that has more than one instance connected to \(C_{l_i}\), then one of them will be non-deterministically chosen;

- (b) **structure changing rules**: the following types of rules are considered:
  - (b1) **membrane division** rule: \([x]_{t_{i_j}} \rightarrow \left[y_1\right]_{t_{i_1}} \ldots \left[y_p\right]_{t_{i_p}} \{g\}\),
    where \(x \in A^+\) and \(y_j \in A^*\); the compartment \(C_{l_i}\) will be replaced by \(p\) compartments; the \(j\)-th compartment, instantiated from the compartment type \(t_{i_j}\) contains the same objects as \(C_{l_i}\), but \(x\), which will be replaced by \(y_j\); all the links of \(C_{l_i}\) are inherited by each of the newly created compartments;
  - (b2) **membrane dissolution** rule: \([t_{l_i}] \rightarrow \lambda \{g\}\);
    the compartment \(C_{l_i}\) will be destroyed together with its links;
  - (b3) **link creation** rule: \([x]_{t_{i_j}}; [t_{l_j}] \rightarrow [y]_{t_{l_i}} - [t_{l_j}] \{g\}\);
    the current compartment is linked to a compartment of type \(t_{l_j}\) and \(x\) is transformed into \(y\); if more than one instance of the compartment type \(t_{l_j}\) exists then one of them will be non-deterministically picked up; \(g\) is a guard that refers to the compartment instantiated from the compartment type \(t_{l_j}\);
  - (b4) **link destruction** rule: \([x]_{t_{i_j}} - [t_{l_j}] \rightarrow [y]_{t_{l_i}}; [t_{l_j}] \{g\}\);
    is the opposite of link creation and means that the compartments are disconnected.

The membrane division is defined slightly differently here compared to [16, 17]. Currently, the right hand side of the rule uses simple multisets with no target compartments, as they were initially introduced in [16, 17].

### 2.2 kP System Execution Strategies

In kP systems the way in which rules are executed is defined for each compartment type \(t\) from \(T\) – see Definition 1 and Remark 1. As in Definition 1, \(\text{Lab}(R)\) is the set of labels of the rules \(R\).

**Definition 7.** For a compartment type \(t = (R, \sigma)\) from \(T\) and \(r \in \text{Lab}(R)\), \(r_1, \ldots, r_s \in \text{Lab}(R)\), the execution strategy, \(\sigma\), is defined by the following

- \(\sigma = \lambda\), means no rule from the current compartment will be executed;
- \(\sigma = \{r\}\), the rule \(r\) is executed;
- \(\sigma = \{r_1, \ldots, r_s\}\) – one of the rules labelled \(r_1, \ldots, r_s\) will be chosen non-deterministically and executed; if none is applicable then none is executed; this is called alternative or choice;
- \(\sigma = \{r_1, \ldots, r_s\}^*\) – the rules are applied an arbitrary number of times (arbitrary parallelism);
- \(\sigma = \{r_1, \ldots, r_s\}^T\) – the rules are executed according to maximal parallelism strategy \(x\);
Kernel P Systems Modelling, Testing and Verification 209

- $\sigma = \sigma_1 \& \ldots \& \sigma_s$, means executing sequentially $\sigma_1, \ldots, \sigma_s$, where $\sigma_i, 1 \leq i \leq s$, describes any of the above cases, namely $\lambda$, one rule, a choice, arbitrary parallelism or maximal parallelism; if one of $\sigma_i$ fails to be executed then the rest is no longer executed;
- for any of the above $\sigma$ strategy only one single structure changing rule is allowed.

Arbitrary parallelism and maximal parallelism for rewriting and communication rules, as well as for structure changing rules (cell division, dissolution), are discussed in [29].

Remark 2. In certain cases the operator $\&$ will be ignored and the sequential execution will be denoted as $\sigma = \sigma_1 \ldots \sigma_s$.

Remark 3. A computation, as usual in membrane computing, is defined as a sequence of finite steps starting from the initial configuration, with the initial multisets distributed in compartments. In each step the rules are selected according to the execution strategy and this is given by the execution strategy in each compartment. The result of a computation will be the number of objects collected in the output compartment. For a kP systems $k\Pi$, the set of all these numbers will be denoted by $M(k\Pi)$.

Remark 4. When a terminal alphabet, $F$, is considered, the result of a computation will be the number of objects from $F$ collected in the output compartment and this will be denoted by $M_t(k\Pi)$

3 kP Systems and Other Classes of P Systems

In this section we will investigate the relationship between kP systems and P systems with active membranes, but other relevant classes of P systems will be also considered, especially those with various applications, such as symport/antiport P systems. In [17, 18] neural-like P systems have been also considered.

3.1 P Systems with Active Membranes versus kP Systems

We study how P systems with active membranes are simulated by kP systems. In this case we are dealing with a cell-like system, so the underlying structure is a tree and we have a set of labels (types) for the compartments of the system. The way the relationship between these P systems is presented in the sequel is a natural extension of the method proposed in [16, 17, 18]. In the previous investigations the set of objects from the output compartment has been mixed up with the rest of the objects of the system. In this investigation we separate the objects corresponding to the output compartment and provide a more consistent notation for the kP system involved. We also deal in this investigation with active membrane systems with an upper bound for the number of active components.
Definition 8. A P system with active membranes of initial degree n is a tuple (see [29], Chapter 11) \( \Pi = (O, H, \mu, w_{1,0}, \ldots, w_{n,0}, R, i_0) \) where:

- \( O \) is an alphabet of objects, \( w_{1,0}, \ldots, w_{n,0} \) are the initial strings in the n initial compartments and \( i_0 \) is the output compartment;
- \( H \) is the set of labels for compartments;
- \( \mu \) defines the tree structure associated with the system;
- \( R \) consists of rules of the following types:
  - (a) rewriting rules: \( [u \rightarrow v]_h^e \), for \( h \in H, e \in \{+, -, 0\} \) (set of electrical charges), \( u \in O^+, v \in O^* \);
  - (b) in communication rules: \( [u]_h^e \rightarrow [v]_h^e \), for \( h \in H, e_1, e_2 \in \{+, -, 0\}, u \in O^+, v \in O^* \);
  - (c) out communication rules: \( [u]_h^e \rightarrow [v]_h^e \), for \( h \in H, e_1, e_2 \in \{+, -, 0\}, u \in O^+, v \in O^* \);
  - (d) dissolution rules: \( [u]_h^h \rightarrow v \), for \( h \in H\setminus\{s\}, s \) denotes the skin membrane (the outmost one), \( e \in \{+, -, 0\}, u \in O^+, v \in O^* \);
  - (e) division rules for elementary membranes: \( [u]_h^e \rightarrow [v]_h^e [w]_h^e \), for \( h \in H, e_1, e_2, e_3 \in \{+, -, 0\}, u \in O^+, v, w \in O^* \);

The rules are executed in accordance with the maxim parallelism, but in each compartment only one of the rules (b)-(e) is executed. In the sequel we assume that the output compartment is neither dissolved nor divided. The result of a computation, obtained in \( i_0 \) is denoted by \( M(\Pi) \).

The following result shows how the computation of a P system with active membranes starting with \( n_1 \) compartments and an upper bound to the number of active compartments can be performed by a kP system using only rewriting and communication rules. A first idea of this result has been given in [16, 17, 18].

Theorem 1. If \( \Pi \) is a P system with active membranes having \( n_1 \) initial compartments and an upper bound to the number of active compartments in any computation, then there exists a kP system, \( k\Pi \), of degree 2 and using only rewriting and communication rules, such that \( M(\Pi) = M(k\Pi) \).

Proof. Let \( \Pi = (O, H, \mu, w_{1,0}, \ldots, w_{n_1,0}, R, i_0) \) be a P system with active membranes of initial degree \( n_1 \). Initially, the polarizations of the \( n_1 \) compartments are all 0, i.e., \( e_1 = \ldots = e_{n_1} = 0 \).

We will build a kP system with two compartments. Compartment \( C_1 \) will capture the contents and rules of all the compartments of \( \Pi \). The other compartment, \( C_2 \) will be associated to \( i_0 \) and this will collect the result.

We will need to keep track of a dynamic system of membranes, since we have dissolution and division of elementary membranes. We will identify a membrane by a pair \((i, h)\) where \( i \in I \) is an index associated with an instance of the membrane and \( h \in H \) is its label. We use the index in addition to the label as the same label might appear several times in the system, especially after a membrane division rule has been applied. We work under the assumption that \( I \) is finite. Its cardinal is equal to the maximum number of active membranes that may appear in any
computation – this is assumed to have an upper limit. We let \( i_0 \in I \) and \( i_0 \in H \). We will denote by \((I \times H)_c\) the currently used pairs \((i, h)\). We assume that for any \((i, h) \in (I \times H)_c\) and \((j, h') \in (I \times H)_c\), we have \( i \neq j \). This way we make sure that the cardinal of \((I \times H)_c\) is always at most the cardinal of \( I \). Whenever a membrane dissolution takes place, its index and label are removed from \((I \times H)_c\). When a membrane division rule is applied the index and label of the divided compartment are removed from \((I \times H)_c\) and two new values of indices with the same label are selected and added to the set \((I \times H)_c\). The tuple \((i_0, i_0)\) is always in \((I \times H)_c\).

We will codify a compartment \([w]_{i_0}^c\) by two tuples \( e, i, h > \) and \( w, i, h > \), with \((i, h) \in (I \times H)_c\), and where, for a multiset \( w = a_1 \ldots a_m, w, i, h > \) denotes \( < a_1, i, h > \ldots < a_m, i, h > \). These tuples appear in \( C_1 \). When \( h = i_0 \) then in addition to the tuples present in \( C_1 \), in \( C_2 \), for \([w]_{i_0}^c\) we have \( e \) and \( w \). For a compartment with label \( h \) and electrical charge \( e \) in \( \Pi \) there is only one tuple \( e, i, h > \in C_1 \), when \( h \neq i_0 \), or an \( e \) in \( C_2 \), otherwise.

By \( p(i, h) \) we denote the parent of the membrane with label \( h \) and of index \( i \). If \( p(i, h) = (i', h') \) it means that the membrane with label \( h' \) and index \( i' \) is the parent of the membrane with label \( h \) and index \( i \). By \( x, p(i, h) \) and \( e, p(i, h) \) we denote the tuples \( e, i', h' > \) and \( e, i', h' > \), respectively.

A new symbol, \( \delta \), will be used for the membrane dissolution and division to control the transfer of objects after these rules have been applied. Hence, we will use the guard

\[
\neg \delta_{\text{all}} := \bigwedge (\neg = \langle \delta, i, h \rangle | i \in I, h \in H).
\]

We also introduce a guard checking that the symbols \( \gamma_1 \) ans \( \gamma_2 \), related with the communication with the output compartment, \( i_0 \), do not appear in the current multiset:

\[
\neg \gamma_{\text{all}} := (\neg = \gamma_1) \land (\neg = \gamma_2).
\]

We construct \( k\Pi \) using \( T = \{ t_1, t_2 \} \), where \( t_j = (R'_j, \sigma_j) \) (where \( R'_j \) and \( \sigma_j \) will be defined later), \( 1 \leq j \leq 2 \), as follows: \( k\Pi = (A, \mu', C_1, C_2, 2) \), where the elements of the system are given below.

- \( \mu' \) is the graph with nodes \( C_1 \), \( C_2 \) and the edge linking them;
- The alphabet is

\[
A = O \cup \{0, 0', +, +', -, -, ', \gamma_1, \gamma_2\} \\
\bigcup \bigcup \{a \in O \cup \{\delta\} \cup \{ e, i, h > | e \in \{0, +, -\} \}\}
\]

- \( C_j = \{t_j, w_{j,0}^0 w_{j,0}''\}, 1 \leq j \leq 2 \) and \( C_2 \) is the output compartment.
  - The initial multiset, \( w_{1,0}^0 w_{1,0}'' \), is given by
    \[
    w_{1,0}^0 = < w_{1,0,1}, h_1 > \ldots < w_{n_1,0}, n_1, h_{n_1} > \bar{w}_{i_0,0}
    \]
    where \( \bar{w}_{i_0,0} \) means that \( w_{i_0,0} \) does not appear in the initial multiset of \( C_1 \) (it will appear in \( C_2 \)).
    \[
    w_{1,0}'' = \{ < e_1, 1, h_1 > \ldots < e_{n_1}, n_1, h_{n_1} > \bar{e}_{i_0} \}.
    \]
where $e_1 = \ldots = e_{n_1} = 0$, for all the initial multisets and initial membranes of $\Pi$, and, similar to the above case, $e_i$ means that $e_i$ does not appear in the initial multiset. The initial multiset $w_{2,0}'w_{2,0}''$, is given by

$$w_{2,0}' = w_{1o,0}, w_{2,0}'' = e_{i0}.$$

Initially, the indices $(I \times H)_1 = \{(1, h_1) \ldots (n_1, h_{n_1})\} \setminus \{(i_0, i_0)\}$ are used in association with compartment $C_1$ and $(i_0, i_0)$ for $C_2$. The currently used indices are $(I \times H)_c = (I \times H)_1 \cup \{(i_0, i_0)\}$.

- $R'_1$ and $R'_2$ contain the rules below.

(a.1) For each $(i, h) \in I \times H \setminus \{(i_0, i_0)\}$ and each rule $[u \rightarrow v]_{h}^e \in R$, $e \in \{+, -, 0\}$, we add to $R'_1$ the rule $< u, i, h > \rightarrow < v, i, h > \{:= e, i, h > \wedge = \delta_{all} \wedge = \gamma_{all}\}$; these rules are applied only when the polarization $e$ appears in the compartment with index $i$ and label $h$ and none of the $(\delta, \gamma, \gamma')$, $\gamma_1$, $\gamma_2$ appears, i.e., no dissolution or division has started and no communication with the output compartment, $i_0$, takes place see below.

(a.2) For $(i, h) = (i_0, i_0)$, we add to $R'_1$ the rule $< u, i_0, i_0 > \rightarrow < v, i_0, i_0 > \{:= e, i_0, i_0 > \wedge = \delta_{all} \wedge = \gamma_{all}\}$ and the rule $u \rightarrow v \{:= e \wedge = \gamma_{all}\}$ to $R'_2$.

(b.1) For each $(i, h) \in I \times H \setminus \{(i_0, i_0)\}$, such that $p(i, h) \neq (i_0, i_0)$, and each rule $u_{1h}^e \rightarrow [v]_{h}^e \in R$, $e_1, e_2 \in \{+, -, 0\}$, we add to $R'_1$ the rule $< u_1, i, h > \rightarrow < e_1, i, h > \rightarrow < v, i, h > < e_2, i, h > \{:= \delta_{all} \wedge = \gamma_{all}\}$; these rules will transform $< u, p(i, h) >$ corresponding to $u$ from the parent compartment to $< v, i, h >$ corresponding to $v$ from the compartment with index $i$ and label $h$; the polarization is changed; as there is only one object $< e_1, i, h >$, it follows that only one single rule corresponding to the compartment can be applied at any moment of the computation.

(b.2) When $(i, h) = (i_0, i_0)$, then the rules added to $R'_1$ are $< u, p(i_0, i_0) >< e_1, i_0, i_0 > \rightarrow < e_2, i_0, i_0 > (\gamma_1, 2)\gamma_1 \{:= \delta_{all} \wedge = \gamma_{all}\}$ and $\gamma_1 \rightarrow \lambda$; and the rules added to $R'_2$ are $e_2' \rightarrow e_2 \{= \gamma_1\}$ and $\gamma_2 e \rightarrow \lambda$, $e \in \{0, +, -\}$. The first rule apart from simulating the communication rule, also introduces $\gamma_1$ in both compartments. In $C_2$ it helps changing the polarization of it and in $C_1$ it helps with the synchronisation of the computation. Then the symbol disappears.

(b.3) When $p(i, h) = (i_0, i_0)$, then we add to $R'_1$ the rules $< u, i_0, i_0 >< e_1, i, h > \rightarrow < v, i, h > < e_2, i, h > (\gamma_2, 2)\gamma_2 \{:= \delta_{all} \wedge = \gamma_{all}\}$ and $\gamma_2 \rightarrow \lambda$. The rule $\gamma_2 \rightarrow \lambda$ is added to $R'_2$. Similar to (b.2), $\gamma_2$ is introduced in both compartments and in $C_2$ it helps removing $u$.

(c.1) For each $(i, h) \in I \times H \setminus \{(i_0, i_0)\}$, such that $p(i, h) \neq (i_0, i_0)$, and each rule $[u]_{h}^e \rightarrow [v]_{h}^e \in R$, $e_1, e_2 \in \{+, -, 0\}$, we add the rule $< u, i, h >< e_1, i, h > \rightarrow < v, p(i, h) > < e_2, i, h > \{:= \delta_{all} \wedge = \gamma_{all}\}$.

(c.2) When $(i, h) = (i_0, i_0)$, then we add to $R'_1$ the rule $< u, i_0, i_0 >< e_1, i_0, i_0 > \rightarrow < v, p(i_0, i_0) > < e_2, i_0, i_0 > (\gamma_2, 2)\gamma_1 \{:= \delta_{all} \wedge = \gamma_{all}\}$. As in (b.2), we use $\gamma_1 \rightarrow \lambda$ in $R'_1$ and $e_2' \rightarrow e_2 \{= \gamma_1\}$ in $R'_2$. We need to
add to \( R' \) the rule \( u \gamma_1 e \to \lambda \). The rules make sure that in \( C_1 \) we simulate the communication rule and in \( C_2 \) \( u \) disappears and the polarization is changed to \( e_2 \).

(c.3) When \( p(i,h) = (i_0,i_0) \), then the rule added to \( R'_1 \) is \(< u,i,h >< e_1,i,h \to < v,i_0,i_0 >< e_2,i,h > (v,2) \{= \delta_{all} \wedge = \gamma_{all} \}. \) This rule simulates the communication rule and introduces \( v \) into \( C_2 \).

(d.1) For each \((i,h) \in I \times H \setminus \{(i_0,i_0)\} \), such that \( p(i,h) \neq (i_0,i_0) \), and each rule \( [u]_h^e \to v \in R, e \in \{+, -, 0\} \), we add to \( R'_1 \) the rule \(< u,i,h >< e,i,h \to < v,i_0,i_0 >< \delta,i,h > (v,2) \{= \delta_{all} \wedge = \gamma_{all} \} \); all the objects corresponding to those from the compartment of index \( i \) and label \( h \) must be moved to the parent compartment - this will happen in the presence of \((\delta,i,h)\) when no other transformation will take place; this is obtained by using in \( R'_1 \) rules \(< a,i,h \to < a,p(i,h) > (= \delta,i,h >) \), \( a \in O \) and \(< \delta,i,h \to \lambda \); the set \( (I \times H)_c \) will change now by removing the pair \((i,h)\) from it.

(d.2) When \( p(i,h) = (i_0,i_0) \), then the rules above will become \(< u,i,h >< e,i,h \to < v,i_0,i_0 >< \delta,i,h > (v,2) \{= \delta_{all} \wedge = \gamma_{all} \} \) and \(< a,i,h \to < a,i,0,i_0 > (a,2) \{= (\delta,i,h) \}, a \in O \).

(e) For each \((i,h) \in I \times H \setminus \{(i_0,i_0)\} \) and each rule \( [u]_h^{e_1} \to [v]_h^{e_2} [w]_h^{e_3} \in R, e_1,e_2,e_3 \in \{+, -, 0\} \); we add to \( R'_1 \) the rule \(< u,i,h >< e_1,i,h \to < v,j_1,h >< e_2,j_1,h > v,j_2,h >< e_3,j_2,h >< \delta,i,h > (v,2) \{= \delta_{all} \wedge = \gamma_{all} \} \) – the pair \((i,h)\) is removed from \( (I \times H)_c \) and two new pairs \((j_1,h)\) and \((j_2,h)\), existing in \( I \times H \), with \( j_1 \neq j_2 \), are added to \( (I \times H)_c \) and one \(< u,i,h \) is transformed into \(< v,j_1,h \) and \(< w,j_2,h \) and their associated electrical charges; then the content corresponding to compartment of index \( i \) and label \( h \) will be moved to those of index \( j_1 \) and \( j_2 \) and the same label \( h \), hence rules \(< a,i,h \to < a,j_1,h > \) \( < a,j_2,h > \) \( = (\delta,i,h >) \), \( a \in O \) are added to \( R'_1 \) when \( j_1 \neq j_2 \); finally, \(< \delta,i,h \to \lambda \) is also included in the set of rules of \( C_1 \); it is clear that only one division rule for the same compartment is applied in any step of the computation.

We note that in \( C' \) there are no rules for dissolution and division as the output compartment is not affected by these rules.

The execution strategy in both compartments, \( C_1 \) and \( C_2 \) is maximal parallelism.

For a sequence of rules applied in \( \Pi \), we have a corresponding sequence of rules in \( k\Pi \). Obviously the objects obtained in the output compartment of \( \Pi \) are the same with those obtained in \( C_2 \) of \( k\Pi \).

### 3.2 P Systems with Symport/Antiport versus kP Systems

The following definition is from [29].

**Definition 9.** A P system (of degree \( d \geq 1 \)) with antiport and/or symport rules is a construct.
\[ \Pi = (O, F, E, \mu, w_{1,0}, \cdots, w_{d,0}, R_1, \cdots, R_d, i_0) \] where

\( O \) is the alphabet of objects; \( F \subseteq O \) is the alphabet of terminal objects; \( E \subseteq O \) is the set of objects occurring in an unbounded number in the environment; \( \mu \) is a membrane structure consisting of \( d \) membranes (usually labelled with \( i \) and represented by corresponding brackets \([i]\), \( 1 \leq i \leq d \)); \( w_i, 1 \leq i \leq d, \) are strings over \( O \) associated with regions \( 1, \cdots, d \) of \( \mu \), representing the initial multisets of objects present in the regions of \( \mu \); \( R_i, 1 \leq i \leq d, \) are finite sets of rules of the form \((u, \text{out}; v, \text{in})\), with \( u \neq \lambda \) and \( v \neq \lambda \) (antiport rule) and/or \((x, \text{out})\) or \((x, \text{in})\), with \( x \neq \lambda \) (symport rules); \( i_0, 1 \leq i_0 \leq d, \) specifies the output membrane of \( \Pi \).

We will show now that one can construct for any symport/antiport \( P \) system a kernel \( P \) system, such that they compute the same result. We will adopt a slightly different way of computing the result of the \( k\Pi \) systems by allowing it to use a set of terminal objects. In this case, according to Remark 4, the result will be given by the number of terminal objects from the output compartment. We can now state the main result of this section.

**Theorem 2.** For any \( P \) system with symport/antiport rules, \( \Pi \), there is a \( k\Pi \) system, \( k\Pi \), using only rewriting and communication rules and having a terminal set of objects, such that \( M(\Pi) = M_t(k\Pi) \).

**Proof.** Let \( \Pi = (O, F, E, \mu, w_{1,0}, \cdots, w_{d,0}, R_1, \cdots, R_d, i_0) \) be a \( P \) system, of degree \( d \), with symport and antiport rules as given by Definition 9.

We construct a \( k\) system \( k\Pi \) of degree one in the following manner. We take one unique compartment \( C_1 \). Apart from the \( d \) membranes in system \( \Pi \), numbered by \( 1, 2, \cdots, d \), we think of the environment as a new membrane, with label \( 0 \).

The \( k\) system we build is \( k\Pi = (A, F', \mu', C_1, 1) \). The alphabet, \( A \), of \( k\Pi \) will consist of objects given by pairs \(<x, i> \in O \times \{0, 1, \cdots, d\} \). For a multiset \( w = a_1 \cdots a_m \) in membrane \( i \) we use the notation \(<w, i>\) for \(<a_1, i>, \cdots <a_m, i>\).

The initial multiset is

\[ w_{1,0} = <w_{1,0}, 1 > \cdots <w_{d,0}, d > \]

i.e., it contains all the pairs having the first element the initial multiset of membrane \( i \) and the second one \( 1 \leq i \leq d \). Initially, the environment associated with \( \Pi \) does not have any other objects apart from those in \( E \). The set of rules, \( R_1' \), of the \( k\) system, includes the rules below.

- If a rule \((u, \text{out}; v, \text{in})\), \( u \neq \lambda, v \neq \lambda \), is in membrane \( i \) with parent \( j \) and \( j \neq 0 \), then we add the rule
  \[ <u, i> <v, j> \rightarrow <u, j> <v, i> \].

- If a rule \((u, \text{out}; v, \text{in})\), \( u \neq \lambda, v \neq \lambda \), is in membrane \( i \) with parent \( j, j = 0 \), then we decompose \( u = u_1 u_2 \) and \( v = v_1 v_2 \), such that \( u_1, v_1 \in (O \setminus E)^* \) and \( u_2, v_2 \in E^* \) and add the rule
  \[ <u, i> <v_1, 0> \rightarrow <u_1, 0> <v, i> \].
If \( u_1 = \lambda \) or \( v_1 = \lambda \) we interpret \( < \lambda, 0 > \) as \( \lambda \), i.e., for \( v_1 = \lambda \) and \( u_1 \neq \lambda \) the rule becomes \( < u, i > \rightarrow < u_1, 0 > < v, i > \).

- If a rule \((u, out), u \neq \lambda\) is in membrane \( i \) with parent \( j \) and \( j \neq 0 \), then we add the rule
  \( < u, i > \rightarrow < u, j > \).
- If a rule \((u, out), u \neq \lambda\) is in membrane \( i \) with parent \( j, j = 0 \), we add the rule
  \( < u, i > \rightarrow < u_1, 0 > < v, i > \), where \( u = u_1u_2 \) with \( u_1 \in (O \setminus E)^* \) and \( u_2 \in E^* \).
  If \( u_1 = \lambda \), then again \( < \lambda, 0 > \) is \( \lambda \), and the rule becomes \( < u, i > \rightarrow \lambda \).
- If a rule \((v, in), v \neq \lambda\) is in membrane \( i \) with parent \( j \) and \( j \neq 0 \), then we add the rule
  \( < v, j > \rightarrow < v, i > \).
- If a rule \((v, in), v \neq \lambda\) is in membrane \( i \) with parent \( j, j = 0 \), we add the rule
  \( < v_1, 0 > \rightarrow < v, i > \), where \( v = v_1v_2 \) with \( v_1 \in (O \setminus E)^+ \) and \( v_2 \in E^* \).
  Note that in this last case \( v_1 \neq \lambda \).

Note that the environment (membrane 0) is treated differently by the above rules. We do not keep track of elements over \( E \) in the environment, which are in an unbounded number, but we must keep track of elements over \( O \setminus E \) in the environment. If an \( u \) must go into the environment, then we decompose \( u = u_1u_2 \) such that \( u_1 \in (O \setminus E)^* \) and \( u_2 \in E^* \), and only \( < u_1, 0 > \) will appear in the right-hand side of the rule. Similarly, if a \( v \) comes from the environment, we have \( v = v_1v_2 \) with \( v_1 \in (O \setminus E)^+ \) and \( v_2 \in E^* \), and \( < v_1, 0 > \) must be consumed by the rule.

The execution strategy of \( k\Pi \) will be maximal parallelism.

The terminal alphabet is \( F' = \{ < a, i_0 > | a \in F \} \). Note that multisets over \( F' \) obtained in \( k\Pi \) will correspond to multisets over \( F \) obtained in membrane \( i_0 \) by \( \Pi \).

Remark 5. It remains an open problem to devise a \( k\Pi \) system with two compartments, where \( C_1 \) reflects the functioning of the entire system, while \( C_2 \) simulates membrane \( i_0 \).

4 Sorting with \( k\Pi \) Systems

Sorting is a central topic in Computer Science (see [25]). A variety of approaches to sorting have been investigated, for different algorithms, and with different P system models. A first approach was [3], in which a BeadSort algorithm was implemented with tissue P systems. Another approach was [6], in which algorithms inspired from sorting networks were implemented using P systems with communication. Other papers ([1], [30]) use different types of P systems, and refine the sorting problem.
to sorting by ranking. A first overview of sorting algorithms implemented with P systems was [2]. A dynamic sorting algorithm was proposed in [7]. The bitonic sort was implemented with P systems [8], spiking neural P systems were used for sorting [10], other network algorithms were implemented using P systems [9]. Another overview of sorting algorithms implemented with P systems is provided by [11]. First implementations of sorting with kP systems were proposed in [16, 17].

The problem can be stated as follows: suppose we want to sort \( x_1, \ldots, x_n \), \( n \geq 1 \), in ascending order, where \( x_i, 1 \leq i \leq n \), are positive integer values. Each such number, \( x_i, 1 \leq i \leq n \), will be represented as a multiset \( a_i^x \), \( 1 \leq i \leq n \), where \( a_i \) is an object from a given set. In the next sections we will present two sorting algorithms using different representations of the sequence of positive integer numbers. More precisely, we start with an algorithm already studied in several other papers, [6, 2] for various types of P systems. Here we implement it using kP systems, by representing each element \( x_i \) by \( a_i^x \), \( 1 \leq i \leq n \). The multisets \( a_i^x \), \( 1 \leq i \leq n \), are stored in separate compartments, \( C_i \), \( 1 \leq i \leq n \) (Section 4.1). In Section 4.2 these positive integer numbers are represented by \( a_i^p \), \( 1 \leq i \leq n \), and stored in one compartment \( C_1 \); an additional one, \( C_2 \), is used for implementation purposes. In Section 4.3 it is used again the representation \( a_i^c \), \( 1 \leq i \leq n \), but a more complex structure of compartments is provided in order to maximise the parallel behaviour of the system implementing the sorting algorithm. The algorithm used in Section 4.1 and Section 4.2 makes comparisons of adjacent compartments by employing a two stage process. In the first stage all pairs “odd-even” are compared \( (C_{2i-1} \) with \( C_{2i} \), \( i \geq 1 \)) and in the second stage all pairs “even-odd” are involved \( (C_{2i} \) with \( C_{2i+1} \), \( i \geq 1 \)).

4.1 Sorting Using kP Systems with an Element per Compartment

The approach presented below follows [16, 17], but stopping conditions have been also considered and the sequence of numbers is obtained in ascending order.

Let us consider a kP system, \( kH_1 \), having \( n \) compartments \( C_i = (t_i, w_{i,0}) \), where \( t_i = (R_i, \sigma_i) \), \( 1 \leq i \leq n \), and a set of objects \( A = \{a, b, c, p, p'\} \). In each compartment, \( C_i \), the initial multiset, \( w_{i,0} \), \( 1 \leq i \leq n \), includes the representation of the positive integer number \( x_i \), i.e., \( a_i^x \), the multiset \( c^{2(n-1)} \) and the object \( p \) for all odd index values, when \( n \) is an even number, and for all odd index values, but the last, when \( n \) is odd. The objects \( p \) stored initially in compartments indexed by odd values indicate that one starts with stage one, whereby “odd-even” compartment pairs are compared first. The multiset \( c^{2(n-1)} \) will be used in a counting process, in each of the compartments, that will help stoping the algorithm when the sorting is complete.

Let us consider for \( n = 6 \) the sequence 3, 6, 9, 5, 7, 8. Then the initial multisets are:

\[
\begin{align*}
w_{1,0} &= a_3 c^{10} p; w_{2,0} = a_6 c^{10}; w_{3,0} = a_0 c^{10} p; w_{4,0} = a_5 c^{10}; w_{5,0} = a_7 c^{10} p; w_{6,0} = a_8 c^{10}.
\end{align*}
\]

As \( n \) is even, \( p \) appears in all compartments indexed by odd values, i.e., \( C_1, C_3, \) and \( C_5 \).
In each compartment $C_i$, $t_i$ contains the following set of rules, denoted $R_i$,

1 ≤ $i$ ≤ $n$,

- $r_{1,i}: a \rightarrow (b, i + 1) \{ \geq p \}$, $i < n$;
- $r_{2,i}: p \rightarrow p'$;
- $r_{3,i}: p' \rightarrow (p, i + 1)$, for $i$ odd and $i < n$, and $r_{3,i}': p' \rightarrow (p, i - 1)$, for $i$ even and $i > 1$;
- $r_{4,i}: ab \rightarrow a(a, i - 1)$, $i > 1$;
- $r_{5,i}: b \rightarrow a$, $i > 1$.

We also consider the rule $r: c \rightarrow \lambda$. This rule is used for implementing the counting process mentioned above. By using the two stage process of comparing “odd-even” pair of compartments and then “even-odd” ones, one needs at most $n − 1$ stages to complete the sorting. As it will be explained below, each stage will involve two steps and consequently after $2(n − 1)$ steps one expects to stop the sorting process.

In each compartment $C_i$, the execution strategy is given by

$$\sigma_i = \{r\} \{r_{1,i}, r_{2,i}, r_{3,i}, r_{4,i}\}^{\top} \{r_{5,i}\}^{\top},$$

if $i$ is odd; for even values of $i$, $r_{3,i}$ is replaced by $r_{3,i}'$. The execution strategy, $\sigma_i$, tells us that a sequence of three sets of rules are executed in each step. The first one indicates that one single rule is applied and then two sets of rules are used, each of them applied in a maximal parallel manner.

We assume that any two compartments, $C_i, C_{i+1}$, 1 ≤ $i$ < $n$, are connected.

In the first step, of the “odd-even” stage, in every compartment one $c$ is removed by applying $r: c \rightarrow \lambda$; then the only applicable rules are $r_{1,i}, r_{2,i}$ in all compartments indexed by an odd value. Given the presence of $p$ in these compartments, rules $r_{1,i}$ move all objects $a$ from each compartment with an odd index value, $i < n$, to the compartment $C_{i+1}$ by transforming them into $bs$ and rules $r_{2,i}$ transforming $p$ into $p'$. In the next step, another $c$ is removed from every compartment and rules $r_{3,i}, r_{4,i}, r_{5,i}$ are then applied. The rules $r_{3,i}$ are applied in compartments with an odd index value and $r_{4,i}$ are applied in compartments with an even index value, this means $p'$ is moved as $p$ from each $C_i$, $i$ an odd value and $i < n$, to compartment $C_{i+1}$ and every $ab$, in each $C_j$, $j$ an even value and $j > 1$, is transformed into an $a$ kept in the compartment and another $a$ moved to $C_{j-1}$. At the end of the step, in each compartment $C_j$, $j$ an even value and $j > 1$, and in accordance with the execution strategy, the remaining $b$ objects, if any, are transformed into $as$. These two steps implement comparators between two adjacent compartments, in this case “odd-even” pairs. If $a^{x_i}$ from $C_i$ and $a^{x_{i+1}}$ from $C_{i+1}$, $i < n$, are such that $x_i > x_{i+1}$ then the multisets $a^{x_i}$ is moved to $C_{i+1}$ and $a^{x_{i+1}}$ to $C_i$. In the next step, the first of the second stage, ps appear in even compartments and the comparators are now acting between pairs of compartments $C_i, C_{i+1}$, where $i$ is even and $i < n$.

Given that the algorithm must stop in maximum $2(n − 1)$ steps, one can notice that in step $2(n − 1)$ the counter, $c$, disappears, i.e., becomes $\lambda$, and the first rule from the execution strategy, $r$, is no longer applicable and then the next sets of
rules are not executed either. Hence, the process stops with the multisets codifying for positive integer values in ascending order.

The table below presents the first four steps of the sorting process.

<table>
<thead>
<tr>
<th>Compartments - Step</th>

</table>

Now, one can state the result of the algorithm presented above and the number of steps involved.

**Theorem 3.** The above algorithm sorts in ascending order a sequence of $n, n \geq 1$, positive integer numbers in $2(n-1)$ steps.

### 4.2 Sorting Using $kP$ Systems with Two Compartments

In this section we use a representation of the positive integer numbers $x_1, \ldots, x_n$ as multisets $a_1^{x_1}, \ldots, a_n^{x_n}$, where $a_1, \ldots, a_n$ are from a given set of objects. We consider a $kP$ system, $kΠ_2$, with two compartments $C_j = (t_j, w_j, 0)$, $1 \leq j \leq 2$, which are linked and $A = \{a_1, \ldots, a_n, c\}$. The initial multisets are $w_1, 0 = a_1^{x_1} \cdots a_n^{x_n} c^{n-1}$ and $w_2, 0 = c^n$.

Finally, the $kP$ system $kΠ_2$ will lead to a multiset $a_1^{x_1} \cdots a_n^{x_n}$ in compartment $C_1$, such that $x_1 \leq \cdots \leq x_n$.

In compartments $C_1$ the rules are

- $R_{1,1} = \{a_i a_{i+1} \rightarrow (a_i, 2)(a_{i+1}, 2) \mid 1 \leq i < n \& i = 1, 3, \ldots\}$;
- $R_{2,1} = \{a_i \rightarrow (a_{i+1}, 2) \mid 1 \leq i < n \& i = 1, 3, \ldots\}$;
- $R_{3,1} = \{a_i \rightarrow (a_i, 2) \mid 1 \leq i \leq n\}$.

We also consider the rule $r : c \rightarrow \lambda$, like in the previous section.

**Compartment $C_2$** has the rules

- $R_{1,2} = \{a_i a_{i+1} \rightarrow (a_i, 1)(a_{i+1}, 1) \mid 1 \leq i < n \& i = 2, 4, \ldots\}$;
- $R_{2,2} = \{a_i \rightarrow (a_i, 1) \mid 1 \leq i < n \& i = 2, 4, \ldots\}$;
- $R_{3,2} = \{a_i \rightarrow (a_i, 1) \mid 1 \leq i \leq n\}$;

and the rule $r$ defined above.

The execution strategies of these compartments are

- $\sigma_j = \{r\} Lab(R_{1,j})^T Lab(R_{2,j})^T Lab(R_{3,j})^T$, $j = 1, 2$.

In compartment $C_1$ one implements “odd-even” comparison steps and in $C_2$ “even-odd” steps. The process starts with compartment $C_1$. The execution strategy in each compartment starts by decrementing the counter (using $r$), then the comparators are implemented by executing first $R_{1,j}$ and then $R_{2,j}$, $j = 1, 2$, both in maximally parallel manner. After that all the pairs $a_i, a_{i+1}$ are sent to the other compartment and when $a^c_d$ and $a^c_{d+1}$ are such that $x_i > x_{i+1}$ then $a_i$ is transformed into $a_{i+1}$ and sent to the other compartment, i.e., $a_i$ and $a_{i+1}$ are swapped.
and sent to the other compartment. In the last part, are moved to the other compartment all the objects $a_i$, $1 \leq i \leq n$, that remained there after comparisons. This is the case when a pair $a_i$ and $a_{i+1}$ has its objects with their multiplicities, $x_i$ and $x_{i+1}$, respectively, in the right order, i.e., $x_i \leq x_{i+1}$.

Clearly after at most $n-1$ steps the objects $a_1, \cdots, a_n$ have their multiplicities in the ascending order and the sorting process stops as $r$ is no longer applicable and the execution strategy is not applicable any more.

**Theorem 4.** The above algorithm sorts in ascending order a sequence of $n, n \geq 1$, positive integer numbers in $n-1$ steps.

One can produce a similar implementation whereby the comparison of two neighbours is made more directly and with simpler rules, but with more complex guards.

In this case we extend the definition of a guard, by allowing $\theta a^n$ to be of the form $\theta f(z)$, where $f(z)$ is a function over the multisets of objects returning a positive integer value. For the current multiset $z$, one can define, for instance, $f_0(z) = |z|_a$. Then a rule $a \rightarrow b(\{> a^k\})$ is applicable to $z$ if the guard is true, i.e., $|z|_a > |z|_b$.

The extended definition of the guard allows us to implement a comparator with simpler rules than in the previous case. We have the pair of integers $x_1, x_2$ represented as $a_1^{x_1}, a_2^{x_2}$. Consider the pair of guarded rewriting rules

$$a_1 \rightarrow a_2 \{> a_1^{f_2(\cdot)}\} \quad \text{and} \quad a_2 \rightarrow a_1 \{< a_2^{f_1(\cdot)}\}$$

where $f_{a_2}(w) = |w|_{a_2}$ and $f_{a_1}(w) = |w|_{a_1}$. Then both guards codify the condition $x_1 > x_2$.

If $x_1 \leq x_2$ the rules are not applicable, while if $x_1 > x_2$, then the $x_1$ copies of $a_1$ are rewritten as $a_2$, and $x_2$ copies of $a_2$ are rewritten as $a_1$, interchanging the values and achieving eventually $x_1 \leq x_2$.

A $kP$ system, $kP_2$, is defined now for sorting the sequence of $n, n \geq 1$, positive integer numbers. It consists of two compartment $C_1$ and $C_2$ which are linked. They have the same initial multisets like $kP_2$. The sets of rules associated with these compartments are

- $R_1$ consisting of three subsets of rules ($R_1$ is responsible for “odd-even” stages):
  - $\{r \mid r : c \rightarrow \lambda\}$;
  - $R_{1,1} = \{a_{i} \rightarrow (a_{i+1}, 2)\{> a_{i+1}^{f_{a_{i+1}}(\cdot)}\} \mid i = 1, 3 \cdots \; \& \; i < n\}$;
  - $R_{2,1} = \{a_{i+1} \rightarrow (a_{i}, 2)\{< a_{i+1}^{f_{a_{i}}(\cdot)}\} \mid i = 1, 3 \cdots \; \& \; i < n\}$;
  - $R_{3,1} = \{a_{i} \rightarrow (a_{i}, 2) \mid i = 1, \cdots, n\}$.

The function $f_{a_{i}}$ is defined $f_{a_{i}}(z) = |z|_{a_{i}}, 1 \leq i \leq n$, for any multiset $z$.

Similarly, one defines $R_2$ in compartment $C_2$, which is used to implement the “even-odd” stage. The execution strategy is given by $\sigma_j = \{r\}Lab(R_{1,j} \cup R_{2,j})^\top Lab(R_{3,j})^\top, j = 1, 2$. 
We suppose the integers to be sorted $x_1, \cdots, x_n$ distinct.

We use a total of $2n^2$ compartments:

- $C_{i,j}$, $1 \leq i, j \leq n$, where each $C_{i,j}$ will be responsible for a comparison;
- $C_i$, $1 \leq i \leq 2n$, where each $C_i$, $1 \leq i \leq n$, will collect the results of comparing $x_i$ to the rest; and $C_i$, $n+1 \leq i \leq 2n$, will collect the sorted result.

The connections between compartments are given by the set of edges

$$E = \bigcup_{i=1}^{n} E_i$$

where

$$E_i = \{(C_i, C_{i,j}) \mid 1 \leq j \leq n\} \cup \{(C_i, C_k) \mid n + 1 \leq k \leq 2n, 1 \leq i \leq n\}.$$

Each $C_{i,j}$, $1 \leq i, j \leq n$, will contain the initial multiset $w_{i,j,0} = a_i^{-} a_j^{-} a$ and the rules

$$r^{l}_{i,j} : a_i \rightarrow a_j F \{ > a_j f_i(\cdot) \}; \quad r^{m}_{i,j} : a_j \rightarrow a_i \{ < a_j f_i(\cdot) \}; \quad r^{r}_{i,j} : a \rightarrow a';$$

where $f_i(z) = |z|_{a_i}$ and $f_j(z) = |z|_{a_j}$.

The execution strategy is $\sigma_{i,j} = \{r^{l}_{i,j}, r^{m}_{i,j}, r^{r}_{i,j}\}^\top$.

Note that the rules $r^{l}_{i,j}, r^{m}_{i,j}$ implement a comparator between $x_i$ and $x_j$, similar to the one of the previous section. The modified comparator produces also a symbol $F$ (False) when $x_i > x_j$, signifying that $x_i \leq x_j$ is false. If the rewriting rules $r^{l}_{i,j}, r^{m}_{i,j}$ and $r^{r}_{i,j}$ have acted, then a single $F$ will be sent to compartment $C_i$ (by using the rule $r_{i,j}$).

In compartment $C_i$, $1 \leq i \leq n$, we have the initial multiset $w_{i,0} = a_i^{-} a$ and the rules

$$r^{l}_{i} : a \rightarrow a'; \quad r^{m}_{i} : a' \rightarrow a'';$$

$$r_{i,0} : a_i \rightarrow (a, n + 1)\{ < F \wedge = a'' \}; \quad r_{i,k} : a_i \rightarrow (a, n + k + 1)\{ = F^k \wedge = a'' \}, 1 \leq k \leq n - 1.$$

The execution strategy is $\sigma_i = \{r^{l}_{i}, r^{m}_{i}, r_{i,0}, \cdots, r_{i,n-1}\}^\top$.

Compartments $C_i$, $n+1 \leq i \leq 2n$, are initially empty and contain no rules.

The functioning of the system is as follows. Initially, in compartments $C_{i,j}$, $1 \leq i, j \leq n$, the rules $r^{l}_{i,j}, r^{m}_{i,j}$, and $r^{r}_{i,j}$ act. If $x_i > x_j$ the values will be interchanged.
and some $F$s will be produced (rules $r_{i,j}^r$, $r_{i,j}^m$ are used), signifying that $x_i \leq x_j$ is false. Also $r_i^m$ is used to transform $a$ in $a'$. If at least one $F$ is produced in $C_{i,j}$, then a single $F$ will be sent to $C_i$, using rule $r_{i,j}$. In parallel, in each compartment $C_i$, $1 \leq i \leq n$, in the first two steps the rules $r_i^r$ and $r_i^m$ are applied.

After these two steps, no rules are applicable in $C_{i,j}$, $1 \leq i, j \leq n$, and in $C_i$, $1 \leq i \leq n$, the rules $r_{i,k}$, $0 \leq k \leq n - 1$, might be applicable, depending on the number of $F$s collected. The number of $F$s tells us how many comparisons $x_i \leq x_j$, $1 \leq j \leq n$, are false. If we have $k$ such $F$s in $C_i$, it means that $x_i$ is greater than exactly $k$ other values, which means that in the sorted order it must be the $(k+1)$-th component. This is accomplished by sending $a^{x_i}$ in $C_{n+k+1}$. The maximum number of $F$s in $C_i$ is $n - 1$ because $C_{i,i}$ will never produce an $F$. If there are no $F$s in $C_i$, this means that $x_i$ is the minimum, and $a^{x_i}$ will be sent to $C_{n+1}$. Compartments $C_{n+i}$, $1 \leq i \leq n$, collect the result of sorting. Each such $C_{n+i}$ will contain at the end of the computation the string $a^{x_1}, \ldots, a^{x_n}$, the $i$-th value in the sorted order. The computation has three steps, the first two ones in which $C_{i,j}$, $1 \leq i, j \leq n$, work, and a third one in which $C_i$, $1 \leq i \leq n$, work.

**Theorem 6.** The above $kP$ system sorts $n$ integers in 3 steps.

### 4.4 Sorting in Constant Time with Membrane Division

The algorithm in the previous section uses only rewriting and communication rules. This solution, although computationally efficient, requires an initial, quite complex, arrangement of compartments and multisets. We present here an algorithm which creates its working space by using membrane division rules.

We want to sort $n$ distinct integers, $x_1, \ldots, x_n$, represented as $a_1^{x_1}, \ldots, a_n^{x_n}$.

We start with a total of $3n$ compartments:

- $C_i$, $1 \leq i \leq n$, where each $C_i$, will collect the results of comparing $x_i$ to the rest;
- $C_i$, $n + 1 \leq i \leq 2n$, will collect the sorted result;
- $C_k$, $2n + 1 \leq k \leq 3n$, such that $C_{2n+i} \subset C_i$, responsible for creating the comparator compartments.

The connections between compartments are given by the set of edges

$$E = \cup_{i=1}^{n} E_i$$

where

$$E_i = \{(C_i, C_{2n+i})\} \cup \{(C_i, C_k) \mid n + 1 \leq k \leq 2n\}, 1 \leq i \leq n.$$
Compartments $C_{i,n+1}$, $1 \leq i \leq 2n$, are initially empty and contain no rules.
Compartments $C_{2n+i}$, $1 \leq i \leq n$, contain an initial multiset $s$, where $s$ is a new object, and the membrane division rules

$$[s]_{2n+i} \rightarrow [a_1^x, a_i^x, a_i^x]_{i,1} \cdots [a_j^x, a_i^x, a_i^x]_{i,j} \cdots [a_n^x, a_i^x, a_i^x]_{i,n}, \ 1 \leq i \leq n.$$  

These rules will generate in each $C_i$ the compartments $C_{i,j}$, $1 \leq j \leq n$. In each $C_{i,j}$ we will have the multiset $a_j^x, a_i^x, a_i^x$, and the rules

$$r'_i : a_i \rightarrow a_j F\{>a_i f_i(z)\} ; \ r''_i : a_j \rightarrow a_i \{<a_j f_i(z)\} ; \ r'''_i : a \rightarrow a';$$
$$r_{i,j} : a' \rightarrow (F,i)\{\geq \} F,$$

where $f_i(z) = |z|_{a_i}$, and $f_j(z) = |z|_{a_j}$.

The execution strategy is $\sigma_{i,j} = \{r'_i, r''_i, r'''_i, r_{i,j}\}$.  

Note that this is the comparator of the previous section, which sends a single $F$ in $C_i$ if $x_i \leq x_j$ is false.

During the first step, in compartment $C_i$ rule $r'_i$ is executed, while in $C_{2n+i}$ the membrane division rule is applied, generating the $C_{i,j}$, $1 \leq j \leq n$. The next three steps are identical to the ones of the previous algorithm.

**Theorem 7.** The above $kP$ system sorts $n$ integers in 4 steps.

### 5 Simulating and Verifying $kP$ Systems

In Section 4, we have illustrated that $kP$ systems provide a coherent and expressive language that allow us to model various systems that were originally implemented by different P system variants. In addition to the modelling aspect, there has been a significant progress on analysing $kP$ systems using various simulation and verification methodologies. The methods and tools developed in this respect have been integrated into a software platform, called kPWorkbench, to support the modelling and analysis of $kP$ systems.

The ability of simulating kernel P systems is an important feature of this tool. Currently, there are two different simulation approaches, kPWorkbench Simulator and FLAME (Flexible Large-Scale Agent Modelling Environment). Both simulators receive as input a $kP$ system model written in $kP$-Lingua and outputs a trace of the execution, which is mainly used for checking the evolution of a system and for extracting various results out of the simulation. The simulators provide traces of execution for a $kP$ system model, and an interface displaying the current configuration (the content of each compartment) at each step. It is useful for checking the temporal evolution of a $kP$ system and for inferring various information from the simulation results.

Another important analysis method that kPWorkbench features is formal verification, requiring an exhaustive analysis of system models against some queries to be verified. The automatic verification of $kP$ systems brings in some challenges as they feature a dynamic structure by preserving the structure changing rules such as membrane division, dissolution and link creation/destruction. kPWorkbench

</tr>
</tbody>
</table>

We now illustrate the usage of the query patterns on the sorting algorithm given in Section 4.1. The other algorithms can be considered in a similar manner. In order to verify that the algorithm works as desired, we have constructed a set of properties specified in kP-Queries, listed in Table 1. The applied pattern types are given in the second column of the table. For each property we provide the following information: (i) informal description of each kP-Query, and (ii) the formal kP-Query using the patterns. The queries given in Table 1 capture that the algorithm given in Section 4.1 works as desired.

We note that both kP–Lingua model and the queries are automatically converted into the languages required by the corresponding model checkers. So, the verification process in kPWORKBENCH is carried out in automatic manner.

The framework employs different verification strategies to alleviate these issues. The framework supports both Linear Temporal Logic (LTL) and Computation Tree Logic (CTL) properties by making use of the SPIN [22] and NuSMV [13] model checkers.

In order to facilitate the formal specification, kPWORKBENCH features a property language, called kP-Queries, comprising a list of natural language statements representing formal property patterns, from which the formal syntax of the SPIN and NuSMV formulas are automatically generated. The property language editor interacts with the kP-Lingua model in question and allows users to directly access the native elements in the model, which results in less verbose and shorter state expressions, and hence more comprehensible formulas. kP-Queries also features a grammar for the most common property patterns. These features and the natural language like syntax of the language make the property construction much easier.

Some of the commonly used patterns are “next”, “existence”, “absence”, “universality”, “recurrence”, “steady-state”, “until”, “response” and “precedence”. The details can be found in [21].
6 Testing kP Systems Using Automata Based Techniques

In this section we outline how the kP systems obtained in the previous sections can be tested using automata based testing methods. The approach presented here follows the blueprint presented in [24] and [15] for cell-like P systems. We illustrate our approach on kΠ₁, the application of our approach on the other kP system modeling sorting algorithms is similar.

Naturally, in order to apply an automata based testing method to a kP model, a finite automata needs to be obtained first. In general, the computation of a kP system cannot be fully modelled by a finite automaton and so an approximate automaton will be sought. The problem will be addressed in two steps.

• Firstly, the computation tree of a P system will be represented as a deterministic finite automaton. In order to guarantee the finiteness of this process, an upper bound \( k \) on the length of any computation will be set and only computations of maximum \( k \) transitions will be considered at a time.

• Secondly, a minimal model, that preserves the required behaviour, will be defined on the basis of the aforementioned derivation tree.

Let \( M_k = (A_k, Q_k, q_{0,k}, F_k, h_k) \) be the finite automaton representation of the computation tree, where \( A_k \) is the finite input alphabet, \( Q_k \) is the finite set of states, \( q_{0,k} \in Q_k \) is the initial state, \( F_k \subseteq Q_k \) is the set of final states, and \( h_k : Q_k \times A_k \rightarrow Q_k \) is the next-state function. \( A_k \) is composed of the tuples of multisets that label the transition of the computation tree. The states of \( T_k \) correspond to the nodes of the tree. For testing purposes we will consider all the states as final. It is implicitly assumed that a non-final “sink” state \( q_{sink} \) that receives all “rejected” transitions, also exists.

Consider \( kΠ₁ \), the kP system in section 4.1, \( n = 6 \) and the sequence to be sorted 3, 6, 9, 5, 7, 8. Then the initial multisets are:

\[
\begin{align*}
& w_{1,0} = a^3c^{10}p; \quad w_{2,0} = a^6c^{10}; \quad w_{3,0} = a^9c^{10}p; \quad w_{4,0} = a^5c^{10}; \quad w_{5,0} = a^7c^{10}p; \quad w_{6,0} = a^8c^{10}.
\end{align*}
\]

As \( kΠ₁ \) is a deterministic kP system, there are no ramification in the computation tree. For \( k = 3 \), this is represented below.

<table>
<thead>
<tr>
<th>Compartments - Step</th>
<th>( C_1 )</th>
<th>( C_2 )</th>
<th>( C_3 )</th>
<th>( C_4 )</th>
<th>( C_5 )</th>
<th>( C_6 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>( r )</td>
<td>( r_{3,1} )</td>
<td>( r_{3,2} )</td>
<td>( r )</td>
<td>( r_{1,5} )</td>
<td>( r_{2,5} )</td>
</tr>
<tr>
<td>1</td>
<td>( r )</td>
<td>( r )</td>
<td>( r_{4,2} )</td>
<td>( r_{3,3} )</td>
<td>( r_{4,4} )</td>
<td>( r_{5,4} )</td>
</tr>
<tr>
<td>2</td>
<td>( r )</td>
<td>( r )</td>
<td>( r )</td>
<td>( r_{1,2} )</td>
<td>( r_{2,2} )</td>
<td>( r_{2,3} )</td>
</tr>
<tr>
<td>3</td>
<td>( r )</td>
<td>( r )</td>
<td>( r )</td>
<td>( r )</td>
<td>( r )</td>
<td>( r )</td>
</tr>
</tbody>
</table>

Let us denote

\[
\begin{align*}
\alpha_1 &= (r_{3,1}r_{2,1}r, r, r_{1,3}r_{2,3}r, r, r_{1,5}r_{2,5}r), \\
\alpha_2 &= (r_{3,1}r_{3,2}, r_{3,3}, r_{4,4}r_{5,4}r, r_{3,5}r_{4,6}), \\
\alpha_3 &= (r, r_{3,2}r_{4,2}, r, r_{3,3}r_{4,2}, r, r_{2,6}), \\
\alpha_4 &= (r, r_{3,2}, r_{3,3}r_{5,3}, r_{3,4}, r_{1,5}r_{5,5}, r_{4,6}).
\end{align*}
\]
Then, for \( k = 3 \), \( M_k = (A_{k}, Q_{k}, q_{0,k}, F_{k}, h_{k}) \), where
\[
A_{k} = \{ \alpha_1, \alpha_2, \alpha_3, \alpha_4 \}, \quad Q_{k} = \{ q_{0,k}, q_{1,k}, q_{2,k}, q_{3,k}, q_{4,k} \}, \quad F_{k} = Q_{k}, \quad \text{and} \quad h_{k},
\]
the next-state function, is defined by: \( h_{k}(q_{i-1,k}, \alpha_i) = q_i,k \), \( 1 \leq i \leq 4 \).

As \( M_k \) is a deterministic finite automaton over \( A_{k} \), one can find the minimal deterministic finite automaton that accepts exactly the language defined by \( M_k \). However, as only sequences of at most \( k \) transitions are considered, it is irrelevant how the constructed automaton will behave for longer sequences. Consequently, a deterministic finite cover automaton of the language defined by \( M_k \) will be sufficient.

A deterministic finite cover automaton (DFCA) of a finite language \( U \) is a deterministic finite automaton that accepts all sequences in \( U \) and possibly other sequences that are longer than any sequence in \( U \) [4], [5]. A minimal DFCA of \( U \) is a DFCA of \( U \) having the least possible states. A minimal DFCA may not be unique (up to a renaming of its states). The great advantage of using a minimal DFCA instead of the minimal deterministic automaton that accepts precisely the language \( U \) is that the size (number of states) of the minimal DFA may be much less than that of the minimal deterministic automaton that accepts \( U \). Several algorithms for constructing a minimal DFCA (starting from the deterministic automaton that accepts the language \( U \)) exist, the best known algorithm [26] requires \( O(n \log n) \) time, where \( n \) denotes the number of states of the original automaton. For details about the construction of a minimal DFCA we refer the reader to [24] and [26].

A minimal DFCA of the language defined by \( M_k \), \( k = 3 \), is \( M = (A_{k}, Q, q_{0}, F, h) \), where \( A = A_{k} \), \( Q = \{ q_{0}, q_{1}, q_{2}, q_{3} \} \), \( F = Q \) and \( h \) defined by: \( h(q_{i-1}, \alpha_i) = q_i \), \( 1 \leq i \leq 3 \) and \( h(q_{3}, \alpha_4) = q_{0} \).

Now, suppose we have a finite state model (automaton) of the system we want to test. In conformance testing one constructs a finite set of input sequences, called test suite, such that the implementation passes all tests in the test suite if and only if it behaves identically to the specification on any input sequence. Naturally, the implementation under test can also be modelled by an unknown deterministic finite automaton, say \( M' \). This is not known, but one can make assumptions about it (e.g. that may have a number of incorrect transitions, missing or extra states). One of the least restrictive assumptions refers to its size (number of states). The \( W \)-method [12] assumes that the difference between the number of states of the implementation model and that of the specification has to be at most \( \beta \), a non-negative integer estimated by the tester. The \( W \)-method involves the selection of two sets of input sequences, a state cover \( S \) and a characterization set \( W \) [12].

In our case, we have constructed a DFCA model of the system and we are only interested of the behavior of the system for sequences of length up to an upper bound \( k \). Then, the set suite will only contain sequences of up to length \( k \) and its successful application to the implementation under test will establish that the implementation will behave identically to the specification for any sequence of length less then or equal to \( k \). This situation is called conformance testing for bounded sequences. Recently, it was shown that the underlying idea of the \( W \)-method can also be applied in the case of bounded sequences, provided that
the sets $S$ and $W$ used in the construction of the test suite satisfy some further requirements; these are called a proper state cover and strong characterization set, respectively [23]. In what follows we informally define these two concepts and illustrate them on our working example. For formal definitions we refer the reader to [23] or [24].

A proper state cover of a deterministic finite automaton $M = (A, Q, q_0, F, h)$ is a set of sequences $S \subseteq A^*$ such that for every state $q \in Q$, $S$ contains a sequence of minimum length that reaches $q$. Consider $M$ the DFCA in our example. Then $\lambda$ is the sequence of minimum length that reaches $q_0$, $\sigma_1$ is a sequence of minimum length that reaches $q_1$, $\alpha_1 \alpha_2$ is a sequence of minimum length that reaches $q_2$, $\alpha_1 \alpha_2 \alpha_3$ is a sequence of minimum length that reaches $q_3$. Furthermore, we can use any input symbol in $A \setminus \{\alpha_1\}$ to reach the (implicit) “sink” state, for example $\alpha_2$. Thus, $S = \{\lambda, \alpha_1, \alpha_1 \alpha_2, \alpha_1 \alpha_2 \alpha_3, \alpha_2\}$ is a proper state cover of $M$.

A strong characterization set of a minimal deterministic finite automaton $M = (A, Q, q_0, F, h)$ is a set of sequences $W \subseteq A^*$ such that for every two distinct states $q_1, q_2 \in Q$, $W$ contains a sequence of minimum length that distinguishes between $q_1$ and $q_2$. Consider again our running example. $\lambda$ distinguishes between the (non-final) “sink” state and all the other (final) states. A transition labelled $\alpha_1$ is defined from $q_0$, but not from $q_1$, $q_2$ or $q_3$, so $\alpha_1$ is a sequence of minimum length that distinguishes $q_0$ from $q_1$, $q_2$ and $q_3$. Similarly, $\alpha_2$ is a sequence of minimum length that distinguishes $q_1$ from $q_2$ and $q_3$ and $\alpha_3$ is a sequence of minimum length that distinguishes between $q_2$ and $q_3$. Thus $W = \{\lambda, \alpha_1, \alpha_2, \alpha_3\}$ is a strong characterization set of $M$.

Once we have established the sets $S$ and $W$ and the maximum number $\beta$ of extra states that the implementation under test may have, a test suite is constructed by extracting all sequences of length up to $k$ from the set

$$S(A^0 \cup A^1 \cup \ldots \cup A^\beta)W,$$

where $A^i$ denotes the set of input sequences of length $i \geq 0$.

Note that some test sequences may be accepted by the DFCA model - these are called positive tests - but some others may not be accepted (they end up in the (non-final) “sink” state) - these are called negative tests.

### 7 Conclusions

In this paper, we have investigated the relationships between kP systems, on the one hand, and active membrane systems with polarization and symport/antiport membrane systems, on the other hand. We have also illustrated the modeling power of kP systems by providing a number of kP system models for sorting algorithms. We have also discussed the problem of testing systems modelled as kernel P systems and proposed a test generation method based on automata. Namely, we have outlined how the kP systems can be tested using automata based
testing methods. Furthermore, we have shown how formal verification can be used to validate that the given models work as desired.

We have also begun a study on the ability of kP systems to simulate other particular classes of P systems. We have presented here the case of P systems with active membranes, and P systems with symport/antiport rules.

In future studies we aim to connect kP systems with other classes of P systems, especially those utilised in various applications, and to show how other problems can be solved, tested and verified by using kP systems.
